ABSTRACT

Anti-platelet therapy is indicated for patients with thromboembolic diseases such as Myocardial infarction, Diabetes, Angina etc. It is not uncommon for such patients to present with dental problems requiring extraction. Continuing anti-platelet therapy during surgical procedures increases the risk of hemorrhage while discontinuing increases the risk of life threatening thromboembolic events. This article aims in evaluating the need to stop aspirin prior to dental extraction.

Key words: Aspirin, Dental Extraction, Anti-platelet therapy, Thromboembolism

INTRODUCTION

Cardio-vascular diseases account for the highest mortality and morbidity worldwide1. With increasing awareness and health consciousness, there is a striking decrease of cardiovascular mortality with the introduction of preventive and maintenance antiplatelet therapy2. Acetyl Salicylic Acid (ASA), generically known as Aspirin, was developed in 1897 and is one of the world’s safest and cheaper drugs with proven efficiency for over 100 years3. It is used clinically as analgesic, anti-pyretic, anti-inflammatory agents and as a medication to prevent platelet aggregation4. Aspirin affects clotting by inhibiting platelet aggregation but they do so by a variety of different mechanisms. Aspirin irreversibly acetylates cyclooxygenase, inhibiting the production of thromboxane A2. This results in decreased platelet aggregation by adenosine diphosphatase and collagen4. It interferes with platelet function and lasts for the lifetime of the platelet, approximately, 8-11 days5. There is considerable conflicting opinion regarding the exact time of stopping aspirin prior to invasive surgical procedure. Various authors recommended stopping aspirin pre operatively. The timing to stop aspirin ranges between 24 hours to 7-10 days. On the contrary, some authors recommended not stopping aspirin pre operatively6.

MATERIALS AND METHODS

Aims & Objectives: To evaluate the need to stop Aspirin therapy prior to dental extraction.

Search Strategy: A systematic search of literature was done using the PubMed Database, MEdical Subject Headings using keywords: “Aspirin and Dental extraction” and 84 articles were reported. Following inclusion and exclusion criteria was then devised to meet the above said aims and objectives.

Inclusion criteria: Clinical trials involving dental extractions in patients under aspirin therapy.

Exclusion criteria: Clinical trials involving dental extractions in patients under anti-platelet therapy other than aspirin.

Based on the above mentioned criteria, 17 articles were selected and were reviewed for selecting appropriate clinical trials.

RESULTS AND DISCUSSION

Literature review reveals that clinical trials involving dental extraction and anti platelet therapy started in 1970 and it is still going on. Studies conducted in 1970s by Lemkin et al6 and Mc Gaul et al24 have documented that there is increased postoperative bleeding after dental extraction and recommended to discontinue aspirin25. Few authors recommended stopping aspirin 7 days preoperatively26, 27. Sonis et al further stated that only the production of newer platelets will be able to overcome the inhibiting effect of aspirin27. Few other authors recommended stopping aspirin for 3 days or lesser than that28, 29, 30. The rationale for such recommendation is that, after 3 days of interruption of aspirin, sufficient number of newer platelets will be present in the circulation for effective hemostasis28, 31. On the other hand, there are various authors who recommended not stopping aspirin therapy prior to dental extraction6-33. There is no indication to stop aspirin therapy prior to invasive dental procedures as any postoperative bleeding if present can be easily managed by local hemostatic measures35. Oral hemostatic measures can be taken to control bleeding after tooth extraction by suturing the socket and by packing gauze bite firmly for 15-30 minutes13. Resorbable gelatin sponge, oxidized cellulose, microfibrillar collagen can also be used. If still bleeds, tranexamic acid can be applied topically34. There are also several other factors that needs to be assessed in patients undergoing anti platelet therapy prior to invasive surgical procedure such as patient’s inherent risk factors for bleeding, invasive potential of the surgical procedure, and potential risk of thromboembolic
event if antiplatelet therapy is stopped\textsuperscript{35}. Therefore, it is advised that a dental clinician should take into consideration all the above said factors before decision making. It is also advised to take physician’s opinion before the surgical procedure. The results have been tabulated in Table 1.

**CONCLUSION**

It is recommended that the patients need not stop aspirin therapy prior to dental extraction when the event of hemorrhagic risk is less likely and when hemorrhage can be easily managed by local hemostatic measures.

Dental extractions can be safely performed in patients receiving single or dual antiplatelet therapy when appropriate local hemostatic measures are taken.

Tooth extractions can be safely performed while patients continue to receive combined anticoagulant-aspirin therapy.

It is a safe practice to perform simple extraction of 1 tooth in patients taking 75-150 mg aspirin daily.

Single tooth extraction by intra alveolar method in patient on continued aspirin therapy is a safe procedure.

There was no indication to discontinue aspirin for the elderly before a single non-impacted tooth extraction.

There is absolutely no need to discontinue antiplatelet therapy for any ambulatory dental procedure.

between patients who continued ASA therapy versus patients who suspended their ASA therapy.

Compared to controls the risk of prolonged immediate bleeding was higher in patients on dual antiplatelet therapy than on aspirin alone.

Dental extractions can be safely performed in patients receiving single or dual antiplatelet therapy when appropriate local hemostatic measures are taken.

Tooth extractions can be safely performed while patients continue to receive combined anticoagulant-aspirin therapy.
