ABSTRACT

The poly (ADP-ribose) polymerase-1 (PARP-1) is an abundant nuclear protein involved in DNA repair and programmed cell death. Substituted 5(H) phenanthradin-6-one analogs were found to be potent PARP-1 inhibitors. Semiempirical methods were used to estimate various physicochemical parameters. The hydration energy (HE), ionization potential (IP), electrophilic index (ω) and partition coefficient (LogP) were resulted as independent variables for inhibitory activity of the analogs. The overall increase of HE, IP, and EI and overall decrease of LogP enhance the efficacy of inhibitory nature of these analogs to PARP-1. Docking studies of 5(H) phenanthradin-6-one analogs with PARP-1 were also performed in support of the findings of QSAR studies. Analysis of results of both QSAR and docking studies suggested that remarkable inhibitory activity is exhibited by molecules **9b**, **10b1** and **10b2**. The hydrogen bond interactions along with hydrophobic and electrostatic interactions are mapped to confirm their potencies.

Keywords: Computational study, structure based methods

INTRODUCTION

The PARP (ADP-Ribose) polymerase-1 family consists of 17 members (10 putative). They have all very different structures and functions in the cell. The members that have confirmed PARP activity are PARP-1 (Fig.2), PARP-2, VPARP (PARP-4), Tankyrase-1 and -2 (PARP-5a or TNKS, and PARP-5b or TNKS2). Others include PARP-3, PARP-6, TIPARP (or "PARP7"), PARP-8, PARP-9, PARP-10, PARP-11, PARP-12, PARP-14, PARP-15, and PARP-16. PARP-1 (Poly (ADP-ribose) polymerase-1) is nuclear DNA repair enzyme as component of base excision repair complex. PARP-1 is also known as NAD⁺ ADP-ribosyltransferase-1 or poly (ADP-ribose) synthase-1 is an enzyme that in humans is encoded by the PARP-1 gene¹. It is a protein involved in a number of cellular processes involving mainly DNA repair and programmed cell death. PARP-1 is also involved and finds applications in differentiation, proliferation, and tumor transformation, may participate in the path physiology of type I diabetes². It is theorized that PARP-1 inhibitors may prove highly effective therapy for cancers with BRCAness, due to the high sensitivity of the tumors to the inhibitor and the lack of deleterious effects on the remaining healthy cells with functioning BRCA HR pathway. This is in contrast to conventional chemotherapies which are highly toxic to all cells and can induce DNA damage in healthy cells, leading to secondary cancer generation^{3,4}.

A common structural feature for the classical PARP-1 inhibitors is a carbamide attached to an aromatic ring or

a fused aromatic aromatic lactam or imide⁵. Most of these inhibitors are structurally planar and show limited solubility in both organic and aqueous solvents.

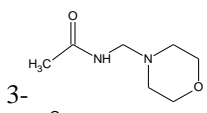

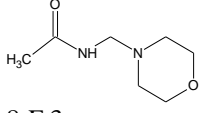

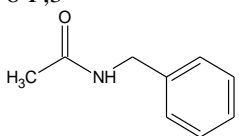

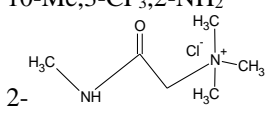

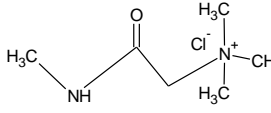

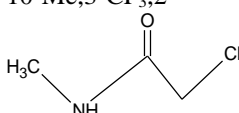

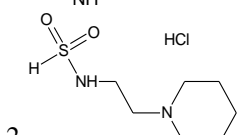

5[H] phenanthradin-6-ones (figure 3 and table 1) was initially identified as a moderate PARP-1 inhibitor⁶. In vivo testing of this compound is hindered by its poor solubility in bio-compatible vehicles. It was also found to cross inhibitor heterophil arginine ADP-ribose transferase (IC-%50- 47 μ m)⁷. Recently, to improve the efficacy of this class of inhibitors appropriate substituent(s) onto 5[H] phenanthradin-6-ones were made, the **29** analogs were synthesized.

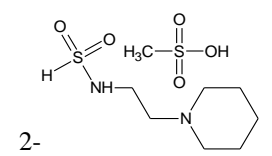

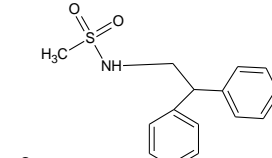

It prompted us to carry out molecular modeling studies for arriving the best chemical improvement to have high inhibitory efficacy of 5[H] phenanthradin-6-one analogs. It is an attempt to elucidate the QSAR study of 5[H] phenanthradin-6-one analogs as PARP-1 inhibitor by using different physicochemical parameters like ionization potentials(IP), hydration energy(HE), polarisability (Pol),

LogP, etc... Recently Lien et al.⁸ have reported on QSAR study of phenols with antioxidant activity by employing descriptors calculated by semi empirical methods AM1 and PM3 (Table 2, 3). A theoretical study of phenolic compounds with antioxidant property was also made on quantitative basis in which four computational methods density functional (DF), HF (Hartree-Fock) and AM1 and PM3 were employed to explore and determine various electronic descriptors with better accuracy to make the necessary improvement in the QSAR models. Vertical ionization potentials (IPv's), electrophilic index (ω), Ionization potential (IP), electron affinity (EA), electronegativity (χ), hardness (η), softness (S), polarisability (Pol) charges and other properties were obtained for 41 phenolic compounds which have antioxidant activity⁸⁻¹⁰.

To correlate the biological activity of 5[H] phenanthradin-6-one analogs with ionization potentials, electron affinity, electronegativity, hardness (η), partition coefficient (LogP), softness (S), hydration energy (HE) and polarisability (Pol) from computational methods AM1 and PM3 (Table 6,7). GOLD and Argus lab 4.0.1 is Molecular modeling and Drug Docking software's¹¹⁻¹². This helps in computational virtual screening to find the lead compounds. Molecular docking started with Fischer's lock and key theory, where, every receptor has its unique ligand to catalyze the reaction.

Computational Methodology Calculations

Data Set

The physicochemical parameters, such as vertical ionization potentials (IPv's) electron affinity (EA), electronegativity (χ), hardness (η), softness (S), electrophilic index (ω), partition coefficient (LogP), charges, hydration energy (HE) and polarisability (Pol) were obtained for 26 5[H] phenanthradin-6-one compounds which have PARP-1 inhibitory activity.

Molecular Structure Building

A series of compounds tested for inhibitory activity was selected for the present study and the program of window Hyperchem software inc.¹³ was used in modeling studies. The molecules were generated and the energy was minimized using molecular modeling pro. The window version software SPSS10¹⁴ was used in the regression analysis.

Building of QSAR Models

QSAR technique was applied to the analogs of 5[H] phenanthradin-6-ones that were varied at the "R" position. The suitable descriptors or parameters for the compounds,

time. The IP_v are calculated as the energy differences between a radical cation and the respective neutral molecule; IP_v ($E_{\text{cation}} - E_{\text{neutral}}$)_{DFT} and Koopman's theorem (IP_v = $-\epsilon_{\text{HOMO}}$). The electron affinity are computed as the energy differences between a neutral form and the anion molecule; EA = $E_{\text{neutral}} - E_{\text{anion}}$. The AM1 and PM3-based reactivity parameters are obtained from Eqs. (1) – (4)¹⁸⁻²².

Correlation Analysis

A relation between biological activity, expressed as Log₁/IC₅₀, and the physicochemical parameters and QSAR was analyzed statistically by fitting the data to correlation equations consisting of various combinations of these parameters. The statistical optimization was used to propose the best correlation model.

The matrix association uses the Pearson product moment correlation to measure the degree of linear relationship between two variables. The coefficient assumes a value between -1 and +1. If one variable tends to increase the other decreases, the correlation coefficient is negative. On the other hand, if the two variables tend to increase simultaneously the correlation coefficient is positive. We obtained the correlation matrix between inhibitory activity and respective calculated properties for **26** 5[H] phenanthradin-6-one analogs. The more significant regression models were selected following criteria: The correlation coefficient (R), the Fisher ratio values (F) and the standard deviations (s), standard error estimate (SEE), percentage of effective variable (%EV) and R²adjusted (R²_{adj}).

The best equation was also tested for their predictive power using a cross-validation procedure. The cross-validation is a practical and reliable method for testing this significance. In principle, the so-called "leave-one-out" approach consist in developing a number of models with one sample omitted at the time.

After developing each model, the omitted data is predicted and the differences between actual and predicted reduction potential (y) values are calculated. The sum of squares of these differences is computed and finally the performance of the model (its predictive ability) is given by PRESS (Predictive Sum of Squares) and S_{PRESS} (Standard deviation of cross validation)²³.

The predictive ability of the model was also quantified in terms of the Q²²⁴.

Docking Studies and Validation

The GOLD Score was calculated by defining the site using the list of atom numbers and retaining all the other default parameters. Now a days docking is frequently to predict the binding orientations of small molecules of drug candidates to their protein targets in order to predict the affinity of the small molecules²⁵. The 3D structure of PARP-1 was retrieved from Protein Data Bank (PDB ID **3SE2**) with an X-ray resolution of 2.3Å⁰²⁶. Docking poses were obtained by applying both Gold score and Chemscore, fitness functions available for scoring. As easily interpretable results were obtained based on a recently published, all the results reported in the present paper are referred to the Gold score and Chemscore fitness functions. These complexes were prepared for docking

Table 5: Observed activity and predicted activity values of 5 [H] Phenanthradin-6-one analogs by using **PM3** Eqs.

studies by adding hydrogen atoms, removing water molecules and co-crystallized inhibitors and refined by using the DeepView/SwissPdbViewer3.7(SP5)²⁷. Enzyme-inhibitor interactions within a radius equal to 10 Å centered on information bound inhibitors were taken into explanation. As a conclusive part of docking we expect, generated results should yield RMSD values below 1.5 Å. Successful docking has been performed for the selected set of 26 5[H] phenanthradin-6-one inhibitors and their corresponding Gold score, Chemscore and binding energy values with their respective RMSD have been produced, in the table 8. All docking runs were carried out using standard default settings with a population size of 100, a selection pressure 1.1, a maximum of 100000 operations, number of islands as 5, a niche size of 2, migrate 10, a mutation and crossover rate of 95.

Argus Lab 4.0.1 is Molecular modeling and Drug Docking software. It is very flexible and can imitated crystallographic binding orientations. Argus lab, which provides a user-friendly graphical interface and uses Shape Dock algorithm, was used to carry out docking studies of the PARP-1.

RESULTS AND DISCUSSIONS

Simple linear regression model

The biological activity data and the physicochemical properties IPv, IP, EA, EI, EN, Hard, Soft, LogP, HE and Pol of the 5[H] Phenanthridin-6-one analogs are given in Tables 1-3. The data from these tables were subjected to regression analysis. The Correlation matrices were generated with 26 analogs (Tables 4,4a and 5,5a). The term close to 1 indicates high co-linearity, while the value

below 0.5 indicates that no co-linearity exist between more than the two parameters.

Table 6: Inhibition of Poly (ADP-ribose) Polymerase-1 (PARP-1) GOLD Scores and Arguslabs Energy values of 5 [H] Phenanthradin-6-one analogs.

The perusal of correlation matrix (Table 4a and Table 5a) indicates that HE, IP and EN are the predicted parameters from AM1 method. From regression methods backward, forward, removed and stepwise. HE, EN, and LogP were found to be explainable variables.

The regression technique was applied through the origin using these reasonable parameters.

$$\text{Activity} = 0.198 \times \text{HE} (0.058) - 0.847 \times \text{EN} (0.08) - 0.618 \times \text{LogP} (0.197) \quad (1)$$

N = 26; R = 0.976; R² = 0.952; R²_{adj} = 0.946; %EV = 95.20; SEE = 0.8785;

F = 153.73; Q = 1.1116;

In addition, the plot of observed activity versus predicted activity was not found to be satisfactory. Hence, the predictive capability of the model is not good. Eq.1 show that the values of %EV are less and to improve its value, outliers were sought and eliminated.

After the elimination of the outlier (1b, 1d, 1e, 9c and 9e), a second model was developed. Overall, there is an increase in R and %EV (95.2 – 98.90) values, and a decrease in SEE (**0.8785 - 0.4698**).

$$\text{Activity} = 0.176 \times \text{HE} (0.042) - 0.648 \times \text{LogP} (0.117) + 1.633 \times \text{IP} (0.50) + 1.852 \times \text{EI} (0.215) \quad (2)$$

N = 21; R = 0.994; R² = 0.989; R²_{adj} = 0.986; %EV = 98.9; SEE = 0.4698;

F = 374.145; Q = 2.1194;

Eq.2 is an improved model since it explains the biological activity to the extent of (98.9%). In this way, the predictive molecular descriptors HE, IP, EI and LogP were considered as variables.

From the correlation matrix table, it reveals HE, EN and LogP are found to be explainable variables. A tri parametric QSAR equation with HE, EN and LogP was generated in PM3 method also.

$$\text{Activity} = 0.168 \times \text{HE} (0.048) - 0.85 \times \text{EN} (0.07) - 0.618 \times \text{LogP} (0.197) \quad (3)$$

N = 26; R = 0.981; R² = 0.962; R²_{adj} = 0.957; %EV = 96.2; SEE = 0.7870; F = 193.422; Q = 1.2465;

Eq.3 shows that the values of %EV is less and to improve its value, outliers were sought and eliminated, In addition, the plot of observed activity versus predicted activity was not found to be satisfactory. Hence, the predictive ability of the model is not good. After the elimination of the outlier (**1b, 1d, 1e, 9c and 9e**), a second model was developed.

$$\text{Activity} = 0.166 \times \text{HE} (0.049) - 0.748 \times \text{LogP} [0.137] + 1.896 \times \text{IP} [0.411] + 1.899 \times \text{EI} \quad (4)$$

N = 21; R = 0.992; R² = 0.985; R²_{adj} = 0.981; %EV = 98.5; SEE = 0.5431;

F = 278.984; Q = 1.8268;

In an attempt to investigate the predictive potential of proposed models, the cross-validation parameters (q²_{cv} and PRESS) were calculated and used. The predictive power of the equations was confirmed by leave-one-out (LOO) cross-validation method [28]. Here, compounds are deleted one after another and prediction of the activity of the deleted compound is made based on QSAR model. The cross-validation evaluates the validity of a model by how well it predicts the data rather than how well it fits the data. The cross-validation parameter, q²_{cv}, is mentioned in the respective equations (Table 6 and 7).

$$q^2_{cv} = \frac{(\text{SD} - \text{PRESS})}{\text{SD}}$$

Where the PRESS (predictive residual sum of squares) and SD (standard deviation) values are obtained as

$$\text{PRESS} = \sum (\text{property}_{\text{observed}} - \text{property}_{\text{predicted}})^2,$$

$$\text{SD} = \sum (\text{property}_{\text{observed}} - \text{property}_{\text{mean}})^2.$$

Eq.2 and 4 of AM1 and PM3 methods respectively give a good q²_{cv} values, which should be always smaller than %EV. A model is considered to be significant when q²_{cv} > 0.3.

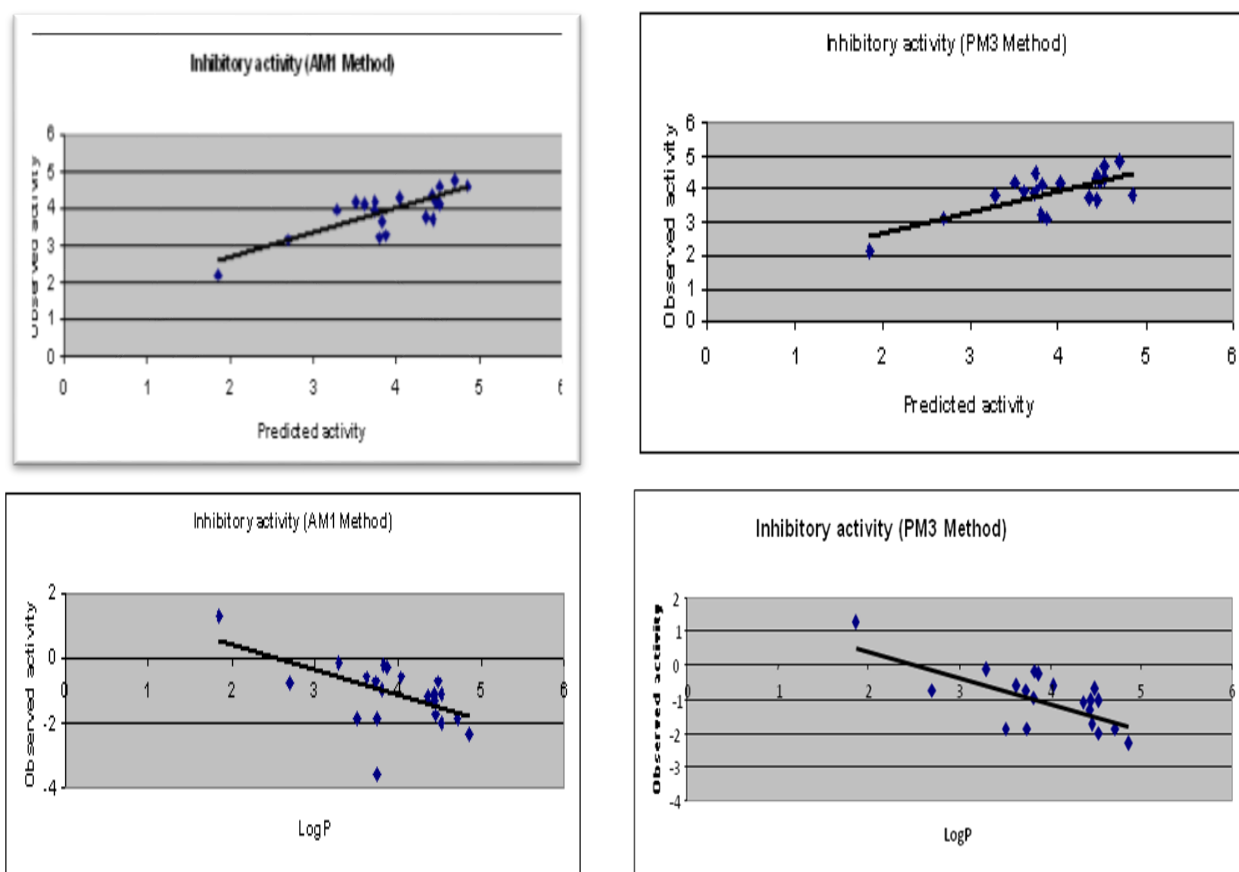

Figure 1: Observed activity Vs Predicted activity.

Another cross-validation parameter, PRESS which is the sum of the squared differences between the actual and that predicted when the compound is omitted from the fitting process, also supports the predictive ability of Eqs.2 and 4. Its value decreases from Eq.1 to Eq.4.

The quality factor Q [23], is defined as the ratio of regression constants (R) to the standard error estimation (SEE), that is, $Q = R/SEE$. This indicates that the higher the value of R, and the lower the value of SEE, the higher is the magnitude of Q and the better will be the correlation. In present case, Q increases from 1.1116 to 2.1194 and 1.2465 to 1.8268 (Eq.1 to 4).

Docking Analysis

The compounds were then docked using each of the three docking software's. The Gold score, Chemscore and binding energy values with their respective RMSD have been produced, from the two docking software's are indicated in **Table 8**. The binding energies obtained in Argus Lab ranged from **-6.3379** to **-10.30 kJ/mol**. The results of CCDC GOLD can be analyzed both Gold score and Chemscore in terms of values ranging from **-29647.95 to 66.00** and **-19.50 to 43.35**.

The docking simulation of the most active 5[H] Phenanthridin-6-one analogs are **1c, 5a1, 9b, 10a2, 10b1** and **10b2** toward PARP-1 (PDB ID 3SE2) showed that the most enzyme-inhibitor complex was stabilized by hydrophobic interactions occurring between the aromatic

moieties of the ligand and lipophilic residues of the binding site.

In particular the 5[H] Phenanthridin-6-one analogs are **1c, 5a1, 9b, 10a2, 10b1** and **10b2** was oriented towards the hydrophobic region lined by ASN1549, ILE1570, GLY1602, SER1641, ASN1614, SER1544, ASN1572, GLU1713, TYR1711, ILE1675, TYR1646 and HET7979. Result of docking studies has proved that the molecule numbered **1c, 5a1, 9b, 10a2, 10b1** and **10b2** shows Gold score, Chemscore and RMSD values as in the **table 8**. All the poses of molecule **1c, 5a1, 9b, 10a2, 10b1** and **10b2** (chosen as best in docking studies) and its interactions in the active pocket of PARP-1 have been illustrated in **figure 8**.

CONCLUSION

The attachment of two optimal substituents onto the core skeleton resulted in the water – soluble compounds, **1c, 5a1**, which exhibits a 5-fold increase in inhibitory activity as compared to the core structure of 5(H)Phenanthradin-6-one **1a**. The variation of substituents at 1-, 2-, 3-, 4-, 8-, and 10- position of the tri cyclic ring of 5[H] phenanthradin-6-ones resulted increase and decrease the inhibitory activity with reference to core. The indicative molecular parameters from both AM1 and PM3 are found to be HE, IP, EI and LogP by a regression analysis. The valid modeled equations 2 and 4 reveal the overall

1c

5a1

9b

10a2

10b1

10b2

increase of HE,IP, and EI and overall decrease of LogP enhance the efficacy of inhibitory nature of these analogs to PARP-1 **figure 4**.

The increase of HE which enhances inhibitory activity indicates replacing of water molecules present in the active site of PARP-1 by interaction. Inhibition trend of 4-substituted compounds appeared 4- amino **9b**>**1a**>4-nitro **9c**.

The electronic nature of 2-or 3- substituents appears a significant affect the inhibition. This was exemplified by the electron withdrawing 2-nitro compound **10a2** and electron donating 2-amino compounds **10b1** and 2, 3-diamino **10b2**. This supported by the indicative parameters IP and EI. The EI is related to LUMO and describes the compounds ability to interact with electron pair donars of active site. This index, quantifies the electrophilic character of the substrates and to describes spatial localization within the molecular volume (at Michael acceptor sites or on other parts of the molecules).The

decrease of inhibitory activity by 5(H) Phenanthradin-6-one analogs with increase of LogP indicates the liphophilic character of the drug candidate is unfavorable. This infers the presence of polar groups of amino acids residues are expected in the active site of PARP-1. The linear dependence of inhibitory activity on LogP is evident from **Figure 6** and **7**. The most active compounds docked successfully into the active site of the inhibited enzyme. Inhibitory activity of the most potent compounds was explained mostly by hydrophobic interactions in **figure 8**. **Figure.5:** Binding orientations of database hit compounds **1c**, **5a1**, **9b**, **10a2**, **10b1** and **10b2**, and crystallographic conformation of PARP-1 active site (PDB ID **3SE2**).Hydrogen bonds are shown in red colour dotted lines.

ACKNOWLEDGEMENTS

One of the authors KRC is very much thankful to the Head, Department of Chemistry, Osmania University, for

providing laboratory facility.
