Abstract
Currently available treatment options for ulcerative colitis (UC) in modern medicine have several adverse effects. Therefore, there is a need to develop safe and effective treatment modalities for ulcerative colitis (UC). Traditional and alternative medicine play an important role in the management of UC as they were developed from the experience of people which passed from one generation to next since history of civilisation. This article presents a review on some reported traditional and alternative medicine for UC.

Key words: Ulcerative colitis, Inflammatory bowel disease, Colitis, Colon, Inflammation, Traditional medicine, Herbal medicine etc.

Introduction
Inflammatory bowel disease (IBD) is a general term for a group of chronic inflammatory disorders of unknown etiology involving the gastrointestinal tract. Chronic IBD may be divided into two major groups, ulcerative colitis (UC) and Crohn's disease (CD), clinically characterized by recurrent inflammatory involvement of intestinal segments with several manifestations often resulting in an unpredictable course1. Ulcerative colitis is an inflammatory chronic disease primarily affecting the colonic mucosa; the extent and severity of colon involvement are variable. In its most limited form it may be restricted to the distal rectum, while in its most extended form the entire colon is involved. However, 80% of the patients present with disease extending from the rectum to the splenic flexure, and only 20% have pancolitis2. Although the causes of IBD remain unclear, considerable progress has been made recently in the identification of important pathophysiologic mechanisms, and further and newer knowledge has been obtained from recent studies concerning their epidemiology, natural history, diagnosis and treatment.

Symptoms
Initial symptoms of ulcerative colitis include diarrhoea, blood in stool, pain, weight loss, arthralgia, fever, loss of appetite, ophthalmopathies, nausea, vomiting, abscesses, fistulae and lymph node swellli. Symptoms of mild, moderate and chronic UC is reported in table 1

Epidemiology
Ulcerative colitis is usually associated with recurrent attacks with complete remission of symptoms in the interim. The disease is more common in Caucasians than in Blacks or Orientals with an increased incidence (three to six fold) in Jewish. Both sexes are equally affected. The peak occurrence of both diseases (UC and CD) is between ages 15 and 35, it has been reported in every decade of life. A familial incidence of IBD is currently recorded. In Asia, Africa and South America, cases of UC is reported less as compared to European country. Breast feeding, smoking and appendectomy are associated with reduced rick of UC. Depression, western diet, left-handedness may increase risk of UC3,4.

Pathophysiology
The cause of UC still remains unclear, but on the basis of research in recent years point to an over stimulation or inadequate regulation of the mucosal immune system as a major pathophysiologic pathway, and particular emphasis has been given to either the study of mucosal inflammation or immunologic reactions. When the disease is active, the lamina propria of the mucosa becomes highly infiltrated with a mixture of acute and chronic inflammatory cells. There is a predominant increase in mucosal Immunoglobulin G (IgG) production, evidence of complement activation, and activation of macrophages and T cells. This immunological activity is associated with the release of a vast array of cytokines, kinins, leukotriene, platelet activating factor (PAF) and reactive oxygen metabolites. These mediators not only serve to amplify the immune and inflammatory response, but they also have direct effects on epithelial function, on endothelial function (which may increase permeability and lead to ischemia), and on repair mechanisms, thus increasing collagen synthesis. In addition, many of the cytokines (interleukins 1 and 6, tumour necrosis factor) will activate an acute phase response, resulting in fever and a rise in serum acute phase proteins3,6,7.

Diagnosis
The diagnosis of UC is made on clinical suspicion and confirmed by biopsy, stool examinations, sigmoidoscopy or colonoscopy, or barium radiographic examination3.

Complication

*Author for Correspondence: yash99yash@gmail.com
Major complications of UC include toxic mega colon, intestinal perforation, and massive bleeding. Toxic mega colon is characterized by a sepsis-like syndrome and extensive distension of the colon (>6 cm). Chronic blood loss leads to microcytic anaemia. Complication of chronic ulcerative colitis may leads to colon cancer. The risk for cancer are generally seen after ten years of colitis.

**Medication**
There is no an effective medicine to cure the UC but the mainstream treatment depends on reduction of the abnormal inflammation in the colon lining and thereby relieves the symptoms of diarrhea, rectal bleeding, and abdominal pain. The treatment depends on the severity of the disease; therefore treatment is adjusted for each individual. Most people with mild or moderate ulcerative colitis are treated with corticosteroids (dexamethasone) to reduce inflammation and relieve symptoms. Near about 25% of patients with UC using steroids become steroid-dependent after one year, and virtually all develop steroid-related adverse events. Other drugs as immune modulators (azathioprine and 6-mercaptopurine) that reduce inflammation by affecting the immune system and amino salicylates are available. However, treatments with amino salicylates medications is typically accompanied with adverse side effects such as nausea, dizziness, changes in blood chemistry (including anaemia and leukopenia) and skin rashes.

**Table: Symptoms of mild, moderate and chronic UC**

The administration of alcohol extract of *Garcinia cambogia* (Clusiaceae) in TNBS-induced colitis rats significantly improved the macroscopic damage and caused substantial reductions in increases in myeloperoxidase (MPO) activity and Cyclooxygenase-2 (COX-2) expression. In addition, *Garcinia cambogia* extract treatment was able to reduce prostaglandin E2 (PGE2) and IL-1beta colonic levels. *Zingiber Officinale* (Zingiberaceae) extract was evaluated for anti-ulcerative colitis activity. Results showed a valuable effect of ginger extract against acetic acid-induced ulcerative colitis possibly by its antioxidant and anti-inflammatory properties.

The protective effects of *Angelica sinensis* polysaccharides could be explained partially by oxidative stress and glutathione (GSH) depletion which are associated with the pathological mechanism of UC. The protective effects of *Angelica sinensis* polysaccharides are closely related to the prevention of oxidative stress, which may occur during neutrophil infiltration in the pathological process of UC.

The effect of polysaccharide obtained from *Rheum tanguticum* (Polygonaceae) on hydrogen peroxide-induced human intestinal epithelial cell injury and they found that, Pre-treatment of the cells with RTP could significantly elevate cell survival. *Rheum tanguticum* polysaccharide may have cytoprotective and anti-oxidant effects against H₂O₂-induced intestinal epithelial cell injury by inhibiting cell apoptosis and necrosis. This might be one of the possible mechanisms of *Rheum tanguticum* polysaccharide for the treatment of ulcerative colitis in rats.

*Camellia sinensis* (Theaceae) extract was found to be effective in the treatment of ulcerative colitis. Both diarrhoea and loss of body weight can be significantly attenuated by the treatment with *Camellia sinensis* extract. The mechanism of action was associated to remarkable amelioration of the disruption of the colonic architecture, significant reduction of colonic (MPO) and tumour necrosis factor- alpha (TNF-α) production.
Aqueous extract of root of *Withania somnifera* (Solanaceae) showed anti-oxidant activity by reducing (Hydrogen peroxyde) \( \text{H}_2\text{O}_2 \) and (Nitric oxie) NO. It has lipid peroxidation inhibition activity. The extracts scored positively on histopathological parameters like necrosis, edema and neutrophil infiltration in TNBS-induced IBD rat model20.

Glycoprotein isolated from *Gardenia jasminoides* has reported effective in (Dextran sodium sulphate) DSS induced UC in mice21.

The ethanol extracts of *Ficus bengalensis* (Moraceae) declined colon mucosal damage index and disease activity index in the colons of rats with IBD22.

*Patrinia scabiosaefolia* (Valerianaceae) are usually used to treat anti-inflammatory diseases, especially for colonic inflammations, virus infections and hepatitis. The root extracts of *Patrinia scabiosaefolia* suppressed weight loss, diarrhoea, gross bleeding, infiltration of immune cells, prevented shortening of colon length and enlargement of spleen size in mice with DSS induced colitis. Histological study indicated that the extracts reduced edema, mucosal damage, the loss of crypts23.

*Avicennia marina* (Acanthaceae) decreased the colonic lipid peroxides, glutathione peroxidase, and serum nitric oxide, lesion score and wet colon weight, and increased the colonic and erythrocyte superoxide dismutase and glutathione levels compared with colitis control24.

Aqueous extract from dry seeds of *Benincasa hispida* (Cucurbitaceae) showed strong antioxidant activity in a dose-dependent manner25. The dried seed extracts produced significant reduction in ulcer index in Wistar albino rats26.

Methanol extract of leaves of *Rhodomyrtus tomentosa* were studied on the production of inflammatory mediators NO and PGE2. The molecular mechanism of methanol extract of leaves of *Rhodomyrtus tomentosa* mediated inhibition, including target enzymes, were studied with RAW264.7, peritoneal macrophage, and HEK293 cells. Additionally, the in vivo anti-inflammatory activity of this extract was evaluated with mouse gastritis and colitis models. Methanol extract of leaves of *Rhodomyrtus tomentosa* clearly inhibited the production of NO and PGE2 in lipopolysaccharide (LPS)-activated RAW264.7 cells and peritoneal macrophages in a dose-dependent manner27.

*Berberis vulgaris* fruit extract (BFE) with three different doses (375, 750, and 1500 mg/Kg) was administered orally or rectally prior to ulcer induction. Berberine chloride (BEC) (10 mg/Kg), prednisolone (5 mg/Kg), hydrocortisone acetate enema (20 mg/Kg) and normal saline (5 mL/ Kg) were considered as respective controls. The tissue was assessed macroscopically for damage scores, area, index and weight/length ratio. They were also examined histopathologically for inflammation extent and severity, crypt damage, invasion involvement and total colitis index. Results indicated that greater doses of oral BFE (750, 1500 mg/Kg) as well as BEC (10 mg/Kg) were effective to protect against colonic damage. By rectal pre-treatment, the extract was only effective to diminish the ulcer index and the efficacy was not significant for mucosal inflammation parameters. In conclusion BFE, which is nearly devoid of berberine, was effective to protect against colitis and this might be attributed to its anthocyanin constituents28.

UC has a lesser prevalence in smokers than non-smokers. Studies using a transdermal nicotine patch have shown clinical and histological improvement29.
A pure curcumin preparation was administered in an open label study to five patients with ulcerative proctitis and five with Crohn’s disease. All proctitis patients improved, with reductions in concomitant medications. Oral Aloe vera taken for 4 weeks produced a clinical response more often than placebo; it also reduced the histological disease activity and appeared to be safe. Bromelain has been found to be effective in improvement of clinical and histologic severity of colonic inflammation in a murine colitis model of IL-10-deficient mice. In a double-blind trial, patient with UC had a reduction in symptoms such as bleeding and remained in remission longer than those who took 20 g of ground Psyllium seeds twice daily with water compared with those who were on the medication mesalazine alone. Guggulsterone significantly reduced the severity of DSS-induced murine colitis as assessed by clinical disease activity score, colon length, and histology. Diammonium glycyrrhizinate could improve intestinal mucosal inflammation in rats and, importantly, reduce expression of TNF-α in inflamed mucosa. In one of clinical studied the treatment of 30 patients with chronic UC, and gave 20 patients a Boswellia gum preparation (900 mg daily divided into 3 doses for 6 weeks), and 10 patients sulfasalazine (3 g daily divided into 3 doses for 6 weeks). They concluded that Boswellia was an effective treatment with few side effects, because 14 out of the 20 patients treated went into remission, and furthermore, 18 out of the 20 patients found an improvement in one or more parameters. In comparison, in the group taking sulfasalazine, 4 out of 10 went into remission, and 6 out of 10 showed improvement in one or more of the above parameters. The modulation of inflammatory molecules by tannins can decrease the damage produced by MMPs. The intestinal permeability and the defect in mucin can leave patients with UC vulnerable to increased inflammation. Tannins can modulate this increase, as well as the pathogenic bacteria associated with UC and the increase in inflammatory molecules. Current research with flavonoids and UC demonstrate a protective effect in mice treated with the colitis-inducing agent, dextran sulphate sodium, so as to prevent the occurrence of colitis. Green tea polyphenols have shown similar benefits in mice by attenuating colonic injury induced by experimental colitis. The research highlights how condensed plant tannins could be an effective treatment option to address each of these contributing factors in the GI inflammation of UC and should be investigated further in clinical trials.

Silymarin is a flavonoid component of Silybum marianum. Silymarin contains antioxidants and inhibits the inflammatory reactions. Silymarin is effective in improving of the inflammation and repair of the colon ulcer induced acetic acid. So, making use of silymarin can be considered as a suggestive way for the colitis treatment.

Terminalia chebula extract (600 mg/kg) showed healing effects against acetic acid-induced colonic damage score and weight when administered orally daily for 14 days.

Bacterial recolonization
Alteration in GIT flora may leads to UC. Probiotics as supplement is beneficial in such cases. The available clinical data shows the role of intestinal micro biota in the pathogenesis of IBD and there by provides an evidence that alteration in the intestinal micro biota with the help of probiotics can be helpful in the treatment of disease. E.g. Bifidobacteria infantis has been found to reduce the inflammatory response of the gut lining by inhibiting the bacteroides. Lactobacillus plantarum has also been reported to be used in IBD. A probiotic formulation containing no of microbes (VSL#3) used in case of ulcerative colitis although its clinical efficacy is not certain. E. coli has also been used in case of ulcerative colitis but its clinical efficacy depends upon its dose.

Iron supplementation
The gradual loss of blood from GIT often leads to anaemia. Adequate disease control usually improves anaemia of chronic disease, but iron deficiency anaemia should be treated with iron supplements. In Ayurveda lauha bhasma and mandur bhasma is recommended in iron deficiency anaemia.

Conclusion
Herbal and alternative medicine play important role in prophylaxis and cure of UC. As the pathophysiology of UC is still not clear but the possible mechanism of herbal and traditional medicine for treatment of UC is described in figure 1. Alkaloids and terpenoids may be used in Ulcerative colitis because of antioxidant and antiulcerogenic activity. Anti ulcerogenic activity may be due to increase secretion of mucus. Phenolics (flavonoids, tannins) and saponins may act by antioxidant, cytoprotective and antiulcerogenic activity. Saponin and Ayurvedic bhasma may act by immunomodulation and anti-inflammatory activity. Prebiotic and probiotic helps in recolonisation of GIT flora. The proposed hypothesis may trigger the researcher to investigate new medicine which can be used in treatment of ulcerative colitis.
