Phytochemical Profile and Antioxidant Activities of Solvent-solvent Fractions of *Haematostaphis barteri* Hook F. (Anacardiaceae) Stem Bark Extracts

Department of Chemistry, Faculty of Sciences, Abubakar Tafawa Balewa University, Bauchi, Nigeria.

Available Online: 12th December, 2015

ABSTRACT

*Haematostaphis barteri* is a plant used in the northern part of Nigeria to manage degenerative diseases such as cancer, anemia and hemorrhage. The dried powdered stem bark was sequentially extracted with soxhlet using solvents of varying polarities. Phytochemical screening of the extracts using standard methods revealed the presence of flavonoids, cardiac glycosides and tannins as the major phytochemicals detected. The scavenging activities of the various crude extracts on 2, 2-diphenyl-1-picrylhydrazyl (DPPH) stable free radical was determined and the result showed very low activities with only aqueous methanol, ethanol and acetone extracts showing inhibitions of 48.2%, 51.3% and 49.9% respectively. But when all of the crude extracts were solvent/solvent fractionated, antioxidant activities of the polar and semi-polar fractions improved appreciably. Presence of polyphenolic compounds such as flavonoids and tannins could be responsible for the antioxidant activity of *H. barteri*.

Keywords: antioxidant, metabolites, purification, free radicals, anticancer

INTRODUCTION

There has been a remarkable insurgence of interest in natural products research over the past decade or so. Secondary metabolites have an extensive history of use as therapeutic metabolites occurring as the following compounds: alkaloids, Anthraquinones, coumarins, essential oils (lower terpenoids and phenylpropanoids), flavonoids, steroids and Terpenoids (cardenolides, diterpenes, iridoids, monoterpenoids, sesquiterpenoids (including sesquiterpene lactones) and triterpenoids. In this research, the stem bark of *Haematostaphis barteri* Hook. f. (Anacardiaceae) was extracted and screened for its phytochemical profiles and for its antioxidant activity. Stem bark of *H. barteri* have been used by traditional healers in northern Nigeria for the management of ailments such as, cancer, stomach ache, and vomiting, anemia and hemorrhoid (Personal interview). The use of this plant in traditional medical practices was corroborated by several published works. Different ethnic groups in Ghana also use the leaves and bark infusion of *H. barteri* in treatment of malaria, hepatitis and sleeping sickness. Similarly, reported the use of stem bark extract of the same plant in management of trypanosomiasis in northern Nigeria. The current research attempted to isolate the bioactive compounds responsible for the aforementioned activities.

MATERIALS AND METHOD

Sample Collection, Identification and Preparation

Identifiable parts of *Haematostaphis barteri* Hook f. (Anacardiaceae) was collected in January, 2015 from North Eastern Nigeria, and conveyed to North East Arid Zone Development Programme (NEAZDP), Gashua, Yobe State, Nigeria where identification was duly made by a plant taxonomist. The stem bark of the plant was collected and shade dried on a tray in a well-ventilated room for several days to ensure complete dryness and to make it free from microbial fermentation. The dried material was pulverized in a clean mortar and pestle into powder.

Extraction of Plant Material

The powdered plant product was subjected to sequential exhaustive soxhlet extraction. Sequential extraction involves using solvents of varying degree of polarities and in this very research extraction followed the sequence; n-hexane, dichloromethane, ethyl acetate, acetone, ethanol and aqueous methanol (1/1 v/v). 100 g of sample was extracted with soxhlet for 6 hours each which yielded six different extract fractions (HX, DCM, EA, AC, EtOH and MeOHaq).

Solvent Fractionation

The recovered crude extracts from the soxhlet extraction were subjected to purification by a sequential solvent/solvent fractionation with a little modification. Each of the selected crude extracts (EA, AC, EtOH and MeOHaq) obtained from the previous sequential soxhlet extraction was subjected to sequential solvent fractionation. During this process the extracts were suspended in a solvent, stirred for a short while and filtered. This was repeated about 3 times until filtrate was colourless, then the next solvent with higher polarity was used for similar process. The procedure continued until

*Author for Correspondence*
Phytochemical analysis was performed on the crude extracts using the standard methods for the qualitative screening of phytocompounds of interest. The phytocompounds that were screened for are: Alkaloids, Flavonoids, Saponins, Tannins, Cardiac glycosides, Anthraquinones, Steroids, Terpenoids, and reducing sugar.

**Test for Alkaloids**

The extract was dissolved in 2ml of chloroform. Concentrated sulphuric acid was carefully added to form a lower layer. A reddish-brown colour at interface indicated steroidal ring (that is aglycone portion).

**Test for flavonoids**

Leibermann/Burchard’s Test: To 2ml of chloroform extract, 2ml of acetic anhydride and few drops of concentrated sulphuric acid were added in a test-tube. Blue-green ring between layers indicate steroids. Pink-purple ring indicate terpenoids.

**Test for saponins**

Flavonoids: Lead acetate test
Saponins: Frothing test
Cardiac Glycosides: Salkowski’s test
Steroids: Leibermann/Burchard’s test
Terpenoids: Leibermann/Burchard’s test
Tannins: Braymer’s test
Anthraquinones: Borntrager’s test
Reducing sugar: Fehling’s test
Phlobatannins

**Phyllopathins**

Aqueous extract was boiled with 1% aqueous hydrochloric acid. Red precipitate was indicative of phlobatannins.

**Antioxidant**

2, 2-Diphenyl-1-picrylhydrazyl Stable Free Radical Scavenging Assay

The capacity of the extract fractions to scavenge the stable free radical 2, 2-diphenyl-1-picrylhydrazyl (DPPH) was monitored according to 11, 12. 2ml of 1mg/ml solution of each extract in 95% methanol were mixed with 2ml of 0.1mM methanolic solution of DPPH. This reaction was conducted in triplicate for right precision of experiment. The mixtures were vortexed thoroughly for one minute at room temperature and incubated for 30 minutes in the dark. Finally, absorbance of each of the mixtures was read at 517nm on a JENWAY 6305 spectrophotometer. The same experiment was conducted with a blank constituted of 95% methanol mixed with the DPPH solution and also with a standard 2, 2-Diphenyl-1-picrylhydrazyl Stable Free Radical Scavenging Assay.
positive control constituted of 1mg/ml of L-(+)-Ascorbic acid solution in 95% methanol. The antioxidant capacity of each extract sample was expressed in terms of percentage inhibition and was calculated as:
\[
\%\text{ Inhibition} = \frac{Ab - Ac}{Ac} \times 100
\]

Where, \(Ab\) = absorbance of blank, \(Ac\) = absorbance of extract or the control.

**RESULT**

In order to come some information on the active components present in the sequential solvent extracts of the stem bark of *Haematostaphis barteri*, different analytical techniques were employed. Firstly, phytochemical screening was performed on each type of solvent extract and result was presented in table 1. Secondly, antioxidant assay using DPPH free radical was performed on all solvent extracts and result was also presented in table 2 and figure 1. Finally, the solvent extracts were purified by solvent-solvent fractionation and the fractions obtained were subjected to further antioxidant assay and the result was presented in table 3 and figure 2.

**DISCUSSION**

The *H. barteri* extracts obtained through sequential soxhlet extraction; DCM, EA, AC, EtOH and MeOHaq were screened for the presence of phytochemicals according to standard methods and, the results were presented in Table 1. Flavonoids, cardiac glycosides and tannins were the prominent phytochemicals in the extracts. Alkaloids were not detected in all of the extracts when tested with Meyer’s reagent. These findings agree with. However, detected alkaloids only in a mixture of dichloromethane/methanol extract but did not detect alkaloids in aqueous extract of the stem bark extract of *H. barteri*. Many types alkaloids such as strychnine and cocaine are poisonous whereas others are used in medicine in controlled concentrations as pain relievers and as antitussive like morphine and codeine especially the steroidal alkaloids. The lead acetate test revealed the presence of flavonoids in almost all of the extracts except in DCM extract. Researchers have repeatedly ascribed antioxidant properties of medicinal plant extracts to flavonoids and phenolic compounds. Isolated flavonoids that were responsible for antioxidant and cytotoxic properties of some plants' extracts reported the isolation of anticancer flavonoids through bioassay guided isolation of antioxidant and cytotoxic compounds. Flavonoids have been shown to have a wide range of biological activities including; antiallergic, antibacterial, anti-inflammatory, antimutagenic, antioxidant, antiproliferative, antiinflammatory, antiviral, hepatoprotective and antihypertensive. The traditional use of the stem bark extract of *H. barteri* as reported in literature and personal interviews for the management of cancer, anemia, hemorrhage and other related illnesses could be due to the presence of flavonoids and other phenolic compounds. Frothing and emulsion tests did not detect saponins in both plants except for slight presence in ethanol and aqueous methanol extracts. This is quite similar to who reported entire absence of saponins in *H. barteri* extracts, but showed presence of saponins in aqueous extract but not in the extract of a mixture of dichloromethane/methanol extracts of *H. barteri*. Holigarna grahamii and pistacia atlanta are medicinal plants and family members with *H. barteri*. Both plants were reported to contain no saponins and some activities of saponins include anti-inflammatory, antiparasitic, and antivirus. It has also been shown to kill tumour cells. Cardiac glycosides were tested for by the Salkowski’s test and found to be positive. But both did not detect glycosides in the stem bark extracts of *H. barteri*. Cardiac glycosides and catecholamine are agents of choice in treatment of congestive heart failure. Extracts from *Digitalis purpurea* and *Digitalis latana* have been used for that purpose. While some cardiac glycosides are entirely poisonous, (for example, oleanderin from *Merium oleander*), some including Digitalis spp. have low therapeutic index, meaning the therapeutic dose is not much lower than the toxic dose. Such glycosides cause intoxication and other complications such as gastrointestinal symptoms (nausea, vomiting, and diarrhea), visual disturbances, neurological symptoms (headache, neuralgia, drowsiness) and cardiovascular failure and arrhythmia. Terpenoids were slightly detected only in DCM and EA extracts. Plant terpenoids exhibit various pharmacological activities such as anti-inflammatory, antitumor, antimalarial, inhibition of cholesterol synthesis, antiviral and antibacterial activities. Terpenoidal saponins isolated from *platyodon grandiflorum* inhibited Hepatitis C virus replication. The plant extracts did not show presence of steroids which was in agreement with. Anabolic steroids have been observed to promote nitrogen retention in osteoporosis and animals with wasting illness. By use of Braymer’s test, tannins were revealed to be abundantly present in all the extracts except in DCM extract. Tannins are known to inhibit pathogenic fungi; the growth of many fungi, yeast, bacteria and viruses were inhibited by tannins. Tannins

have also been reported to exert other physiological effects such as to accelerate blood clotting, reduce blood pressure, decrease serum lipid level, produce liver necrosis and modulate immunoresponse. Plant tannins have also been shown to provide a novel therapeutic option for major factors in the induction of ulcerative colitis. Hydrolysable tannins are potentially toxic to animals. Consumption of feeds containing high levels of hydrolysable tannins causes liver and kidney toxicity and lead to death of animals. Anthraquinones were not detected in all of the plant’s extracts. Anthraquinones are considered to be one of the most active agents in treatment of metastatic breast cancer. Most plants containing anthraquinones possess laxative properties. The derivatives of anthraquinones present in purgative drugs may be dihydroxy phenols and trihydroxy phenols such as chrysophanol and emodins respectively. Reducing sugars were slightly present in AC, EtOH and MeOHaq extracts. The percentage inhibition of the scavenging activities of the crude extracts of H. barteri on DPPH free radical was shown on Tables 2. It shows that acetone, ethanol and aqueous methanol extracts have percentage inhibition of 49.9%, 51.3% and 48.2% respectively. Compared to the standard drug, ascorbic acid which has percentage inhibition of 98% the extracts cannot be regarded as strong antioxidants let along dichloromethane and ethyl acetate extracts. In fact methanol, ethanol and acetone have been found to be more effective in extracting antioxidant compounds from plants. The three solvents have been found to be good in extracting phenolic compounds and flavonoids with aqueous acetone being the best. On fractionating the crude extracts, the resulting fractions (Table 3) showed improved antioxidant activities. Fractions from acetone and methanol gave percentage inhibition very close to the standard drug. However, it had earlier been reported that, methanol has generally been found to be more efficient in extracting lower molecular weight polyphenols while the higher molecular weight flavanols are better extracted with aqueous acetone, whereas ethanol is also a good solvent for the same purpose and safer for human consumption. Some compounds with antitumor activities were isolated based on only their antioxidant properties. Bioassay guided fractionation of active extract of Chorizanthe diffusa using DPPH free radical scavenging assay led to the isolation of one novel compound (flavone) with antitumor property from ethyl acetate fractions. Table 3 shows the percentage inhibition of solvent fractions of H. barteri on DPPH which is quite close to that of the standard ascorbic acid. This means that they could contain bioactive components that elicit antioxidant properties and, perhaps that could
also be the reason why the plant is used traditionally to manage tumor, anemia and hemorrhage.

CONCLUSION

The phytochemical screening of the crude extracts obtained by sequential solvent extraction of dried stem bark of Haematostaphis barteri showed the presence of flavonoids, cardiac glycosides and tannins as the major secondary metabolites in the extracts. The free radical scavenging properties of the extracts were determined quantitatively by the use of 2, 2'-diphenyl-1-picyrlylhydrazyl (DPPH) and result revealed that only acetone, ethanol and aqueous methanol extracts were weakly active with percentage inhibition of DPPH activities of 49.9%, 51.3% and 48.2% respectively. But on purification by solvent/solvent fractionation all fractions from acetone, ethanol and aqueous methanol and some from ethyl acetate gave high percentage inhibition of DPPH activity comparable to standard antioxidant, ascorbic acid. The high antioxidant capacity of the extract fractions could be due to the presence of the phenolic compounds such as flavonoids and tannins.
