ABSTRACT
The plant of castor is widely spread in the Iraqi land, and characterized with containing ricin toxin, which has a very serious effects, and because the seeds of this plant scattered in the agricultural soil and rivers water, which increases the exposure of humans and animals to these beans. Objective: This experiment was designed to study the effect of high concentration of castor bean powder in some physiological and biochemical parameters and changes in some tissues of the body, as well as trying to use doxycycline to reduce the effects of ingestion of these seeds. Materials and Methods: In the experiment, 24 local rabbits were raised and treated in the Animal House of the Faculty of Medicine / AL-Muthanna University, then divided into four groups and treated for three weeks (21 days), Control group: treated with normal saline solution (0.9) orally throughout the experiment, G1: was treated orally with a concentration of 25 mg / kg of castor bean powder daily during the experiment, G2 : orally treated 25 mg / kg of castor bean and 25 mg / kg of doxycycline, G3: orally treated 25 mg / kg of castor powder with 50 mg / kg of doxycycline daily throughout the trial period. Results: The results of the experiment showed significant changes (P <0.05) in all physiological and biochemical blood tests when compared with control group. There was a significant decrease in PCV, Hb, RBC, T.protein and body weights, while demonstrated a significant increase in WBC, Urea, Creatinine, ALT, AST and ALP, with distortions in liver and kidney of animals that treated with Castor beans. In contrast, the treatment with doxycycline and castor beans showed significant improvement reflected by a normal proportion in physiological tests and biochemical tests with improvement in the tissues when compared to control group. Conclusions: It can be concluded from this study that castor bean has high toxic and pathogenic effects that may be dangerous to the life of the organism. Therefore, it is advisable to be cautious of these pills and avoid exposure to them, also recommended to take high concentrations of doxycycline treatment when infected with castor bean poisoning.

Keywords: Castor, Doxycycline, Blood parameters, Histology sections, rabbits.

INTRODUCTION
The plant of castor (Ricinus communis) is a plant from the family of Euphorbia, which consists of leaves with five cloves and seeds containing the world famous oil called castor oil, where the seed contains about 40-50% of its weight oil, which is non-toxic⁴. Castor seeds also contain a substance called ricin, which is highly toxic, dissolves in water and is not soluble in oil, and is considered the deadliest on earth. The ingestion of one fruit is enough to kill an adult in a few minutes⁵. This substance has been considered as a deadly poison by Centers for Disease Control and Prevention (CDC) and has been described as carcinogenic or lethal⁵. Where the death of many cattle when taken for a few seeds of castor as a source of food during the experiment of one of the researchers who faced challenges related to changes in the tissue and damage to some members of the body in animals after the presence of a proportion of proteins in these seeds up to (38-42%), which later found that the content of ricin in each grain reached (9.3 mg / g) and had a clear effect on the cells of the mammalian⁶. Also mentioned⁷ the presence of high toxicity of castor bean during an experiment on mice for several plants showed their toxicity by digestion, and said⁸ Exposure to the castor plant during digestion is more dangerous than inhalation or injection, and digestion of approximately five beads may be lethal dose with the observation that some of this amount is analyzed by the effect of gastric acid⁹. In addition, many researchers found that ricin toxin is one of the deadly toxins used in biological weapons. It has been used in wars after being extracted from castor beans and documented as a deadly toxin by means of digestion and inhalation⁹,¹⁰,¹¹. The risin toxin is found in two units, a series that inhibit the protein synthesis, and B series, which are linked to the Galactose ligand on the cell membrane surface of animal cell¹¹,¹², this type of toxin enters the intestinal region in a chewing or crushing manner leading to serious toxicity symptoms, especially in the gastrointestinal tract GIT¹³, the method of exposure to castor bean has a significant role in the effect of toxin, inhalation of a small amount of ricin toxin leads to severe respiratory damage or death.
which LD50 described in an experiment on mice 3–10 mg/kg when inhaled or injected, and 30 Mg / kg when chewing or digestion of plant castor seeds14. This substance has also shown other symptoms in animals because of its deposition on the leaves of plants used for nutrition such as nausea, diarrhea, vomiting, abdominal pain, inflammation, bleeding in the GIT area, blood decomposition and low sugar215 RNA is analyzed in a base environment leading to the death of the animal cell16, in addition toardy cardia, sinus, irregular heartbeat, arrhythmic pulmonary edema and severe respiratory distress18, as a medical procedure, plasma was substituted for infected children, which resulted in the disappearance of symptoms and regularity of organs9, also noticed15 the presence of an area called Sarcin ricin loop (SRL) which is very important for the work of the ribosome by facilitating the correlation and activating the transmission of GTPases that regulate protein synthesis.

According to some sources, the use of tetracycline treatments may reduce and weaken the toxic effect of ricin in the castor plant and prevent infection in many organs, such as liver and lung7. Other studies indicate that no effective treatment of the toxic effects of ricin in castor beans has been achieved11,15. This study was conducted to investigate the pathological changes resulting from exposure to castor bean to increase the knowledge and health awareness of the plants risk, as well as to test the use of doxycycline to treat or mitigate the pathogenic effects.

MATERIALS AND METHODS

Experiment Design
The experiment was conducted at the Animal House of the Faculty of Medicine at Al-Muthanna University. Twenty-four local male rabbits, weighting (1000-1600g), were used at ages not exceeding one year and three months. They were placed in iron cages and subjected to similar conditions of water, food and temperature. After that the animals were left for a week for adaptive to the study conditions, the concentrations of castor bean (Ricinus communis) and doxycycline were prepared through a series of dilution according to the required concentrations. The animals were then treated orally for three weeks, randomly divided into four main groups (each group 6 animals), as follows: Control group, was treated normal saline (0.9%) daily throughout the experiment period. The first treatment group (G1): The animals were orally treated with 25 mg of castor bean powder per kilogram of body weight per day throughout the experiment. The second treatment group (G2), treated 25 mg of castor powder and 25 mg of doxycycline orally per kilogram of body weight per day throughout the experiment. The third treatment group (G3), the animals were treated with a concentration of 25 mg of castor bean powder and 50 mg / Of doxycycline was given orally per kilogram of body weight per day throughout the trial period.

Physiological and Biochemical tests
The packed cell volume (PCV) and hemoglobin (Hb) was measured according to17, the number of red blood cells (RBCs) and the number of white blood cells (WBCs) were measured18. The level of the biochemical parameters in this study was also measured in several ways, Level of Urea and Creatinine in the blood of treated animals measured by19, while liver function (ALP, AST, ALT) was measured according to20, and the total protein level (T. Protein) was measured in the blood of experimental animals in a method21.

Histological Study
The histological sections of the studied organs in treated animals (liver, kidney and lung) was performed according to method22.

Statistical analysis
Used SPSS program and the probability level 0.05 in the statistical analysis, then T-test to find the significant differences between the treated and control groups23.

RESULTS AND DISSECTION

Physiological tests
The results showed a significant decrease in the most physiological parameters of experimental animals treated with castor bean. Where significant decrease was observed (P <0.05) in Packed cell volume PCV (Fig1) and Hemoglobin (Fig 2) for the first group, also appeared significant decrease for the number of red blood cells RBC (Fig 3) for the animals treated with castor beans when compared to the control group. After treatment with Doxycycline addition to castor beans on doses (25, 50 mg/kg), there were no significant differences in PCV, Hb and RBCs when compared to control group. According to some sources, the treatment of castor bean leads to the decomposition of blood cells in general, which leads to a decrease in red blood cells count and hemoglobin after days of treatment by agglutination and hemolysis24,25, and this decrease may be due to an imbalance in the amount of blood plasma that result from treatment with Castor plant, which results disruption in the work of blood cells and different in natural proportions26, also these changes may be due to the effect of ricin on the liver, bone marrow and the production of erythropoietin from the kidney27 which is the most acceptable reason , this was confirmed by16 the emergence of a decline in the proportions of physiological parameters, especially red blood cells due to histological changes after exposure to castor bean. While the improvement in physiological parameters after treatment with doxycycline may be due to its role as an against to the action of ricin by reducing its toxicity, which reduces tissue and physiological changes within hours of use7.

The results also showed a significant increase (P < 0.05) in the number of white blood cells WBC (Fig 4) for animals treated with castor bean for the first group when compared statistically to the control group, while a slight decrease in the number of white cells was observed after treatment with doxycycline and castor beans in the second group, which did not reach the normal proportions as in the third group when treated with a higher concentration of Doxycycline when comparing the two groups with control group. The increase in the counting of white blood cells in the first group may be due to the
occurrence of high inflammation after treatment with castor beans, which result from the occurrence of pathological changes in many organs, including liver and kidney which emerged clearly in this study. As for the decrease in white blood cells of the second and third groups may be result from the role of doxycycline in the treatment of inflammation and damage in the tissue by its role as anti-inflammatory.

**Biochemical tests**

During the statistical analysis of the results in Biochemical tests was observed that the majority of the tests were observed increased after treatment with castor bean, where the results of liver function enzymes ALT, AST (Fig 5) and ALP (Fig 6) showed significant increase (P <0.05) in the first group when treated with 25 mg / kg of castor beans, there was also a significant increase in these enzymes for the second group treated with doxycycline with a concentration of 25 mg / kg, while no significant difference of these enzymes was shown in the treatment with a higher concentration of doxycycline in the third group when compared with the control group. The researchers reported a rise in liver enzymes when exposed to castor seeds, noting that the proportions of ALT, AST continue to rise when eating five or more beans, which may be due to the effect on the composition of certain tissues including liver and slow to the work of heart muscle. It was also found that the ingestion of castor beans for some adults who ate six of them with a concentration of 25 mg had a significantly higher ALP. These changes may result from apoptosis, which is due to the phospho-calcium imbalance, release of cytokines and the oxidative state of the liver. The second and third groups showed a decrease in hepatic enzymes, which may result from the action of doxycycline on the improvement of disease symptoms by maintaining adenosine acid in the structure of ribosomes and continuous metabolic processes across the membrane in the liver. Maintaining the living cell.

As for kidney function tests, the results showed a significant increase (P <0.05) in the amount of blood urea (Fig 7) and the level of creatinine (Fig 8) after treatment with castor beans in the first group, while there were no significant changes in these tests when treated with castor and doxycycline together for the second and third groups when statistically compared to the control group. Note that the researcher increased the proportion of the functional parameters of the kidney increasingly after swallowing of castor beans to some people reviewed the hospital, which led to the increase in quantity of this substances in the urine also. It was later observed that the ricin-B binds to the Galactose receptors in the renal cell membrane, leading to cell damage and death, thus disrupting the primary functions of the kidney, also said that the treated with castor beans is working to increase the tests of kidney functions, because of the erosion in the tissue or due to lack of urine output. As for the treatment of doxy-cycen in other groups, it has a protective role for the effect of castor bean, which may be due to the prevention of High vascular permeability by vascular endothelium cadherin on epithelial cells, in addition to enhancing the oxidative stress parameters and the vascular permeability of the glomerulus.

The data also showed a significant decrease (P <0.05) in the total protein (T.protein) (Fig 9) and animal weights (Fig 10) treated with 25 mg/kg of castor beans in the first group. In the second group, there was a slight increase in these tests, were not reach the normal rates when treated with doxycycline and castor beans. While the high concentration of doxycycline in the third group showed a high improvement in the total protein and the weights of treated animal bodies, there was no significant difference as for the control group. The increase in total protein by castor bean is due to irregular blood plasma, which causes a decrease in the protein content inside and outside the cell, this deficiency may also be due to the transfer of a quantity of ricin toxin to the Golgi apparatus then to the endoplasmic reticulum and then interact with the ribosome to remove adenosine acid from the RNA structure, which causes a decrease in the function of the protein synthesis. In addition and confirmed a decrease in weights of pregnant rabbit bodies treated with castor beans during 5-9 days, and the cause of the decrease in weight may be due to the damage and bleeding in the gastrointestinal tract (GIT) and low blood sugar levels, which in turn reduces nutrients absorption and decreases the process of protein synthesis. As for the control group, that is not enough alone to treat the poisoning of castor beans because it works on inflammation, but the effect is less on the protein, which is strongly affected by the poison, that is one of the main causes of real damage in tissues, but here use high concentrations of doxycycline found effective and good for treating this type of poisoning in the current study.

**Histological study**

**Liver**

The examination of the tissue sections in the control group showed that the liver consists of hexagonal structures separated by interlobular septum, each lobule has a central vein, regulate the hepatocytes around him with radial shape. In a platelets separated by Hepatic Sinusoids, among these lobules is the portal vein (Image 1). The histological sections of the liver in the first treatment group of castor beans (G1) showed significant damage to the hepatic distribution of hepatic cells around...
the central vein area, which showed expansion and dissection of the endothelium, and appearance of red blood corpuscles in hematopoietic areas is confined.

between hepatic sinusoids, with necrosis of diffuse hepatic cells and release of certain nuclei of the decomposing cells and the appearance of inflammation (Image 2). Some researchers pointed to the effect of ricin toxin on the histological structure of animal livers by influencing the ribosomes in liver cells leading to tissue necrosis\(^{41,42}\), where the accumulation of ricin in the liver and spleen and absorbed by the lymphatic vessels and blood after two hours of eating orally causing damage to the composition of the tissue and shows its toxic effect after that in all cells of the body\(^{43,44}\), addition to this binding of the ricin after digestion of the castor beans with the Mannose surface receptors on the kupffer cells in lining the walls of the hepatic sinusoids causes disseminated intravascular coagulation and hepatocellular necrosis\(^{14,45}\), also mentioned\(^{9}\) the dehydration of the body tissues, especially the liver after exposure to castor seeds, which leads to the death of cells and the incidence of inflammation in nearby tissues, including GIT, and that cell death due to ricin may result from damage to the proteins and lipids of the cell membrane because of the free radicals generated by ricin toxin, which leads to Apoptosis in the cells of endothelium, epithelium, lymphoid and myeloid cells with several organs and organelles in the body\(^{14,29,46}\).

While the use of doxycycline with castor beans in the second treatment group (G2) improved slightly by reducing the expansion of the central vein in which some inflammation and a simple death in hepatocytes, with maintaining some arrangement of radial cells around the
central vein, With some erythrocyte hemorrhage being observed in sinusoids (Image 3). While the histological structure of the liver in the animals of the third group, in which use a higher concentration of doxycycline was a good improvement and a structure closer to the non-treated control group. Where observed the preservation of the radial shape was fully of hepatocytes around the central vein, disappearance of hemorrhagic cells in the sinusoids areas, scarcity of inflammation and absence of cell death (Image 4). Noted (8) that the use of 3-azido-3 doxycycline therapy reduces the effectiveness of ricin toxin A by regulating proinflammatory cytokinase as antiinflammation, antioxidant, inhibitor for Matrex-metallo proteinase and reduced of vascular hyper permeability, Thus playing a role in curbing the action of free radicals47,48.

Kidney

The microscopic tissue sections of control group showed two layers in the structure of the kidney. The inner layer consisting only of convoluted tubules called the medulla, the outer layer containing the Proximal convoluted tubules, Distal convoluted tubules and glomerulus, Which is surrounded by a Bowman capsule called as cortex (Image 5). While the tissue sections of the first group showed, significant changes in the structure of the kidney after the animals were treated with castor powder. A large conglomeration was observed in the basic structure of the glomerulus, the expansion and dissolution of the internal tissue in the Bauman capsule, Distal and Proximal convoluted tubules, breakdown of their cells, addition to appearance of inflammation and spread of dead cells (Image 6). The kidney is one of the most important organs that is directly affected by toxins because of the filtration of blood49, where the onset of cellular death within 48 hours followed by the breakdown of the components of the cell within six days, especially the ribosomes, which leads later to kidney failure6,51, in addition to that ricin causes the oxidative stress of several cells, which confuses several mechanics inside the cell, leading to Apoptosis. It also binds to the glycoprotein on the cell surface, causing damage to the membrane structure and RNA infection, producer of cell death14, as well as high damage resulting from toxicity, which causes Nephritis and kidney necrosis, which ends with renal insufficiency then renal failure30,46.

In the second group, the tissue sections were less affected after treatment with a concentration of 25 mg/kg of doxycycline, although there were satisfactory changes, the conglomerate appeared in the glomerular structure less than in the first group. The dissociation was still present for the lining of the Bowman capsule, As well as cellular necrosis of some tissue (Image 7). While the treatment with a higher concentration of doxycycline (50 mg / kg) and castor powder showed significant improvement in kidney tissue. In the tissue sections of the third group of animals, it was observed that the general structure of kidney tissue was maintained through the clear and distinct regulation of the glomerulus, slight change in lining of Bowman capsule and the integrity of the inner lining of the tubules, as well as the disappearance of many areas of inflammation and death in the cell lines to be closer to the normal model of animals control group, although there are some changes (Image 8). The researcher42 reported that the treatment with doxycycline has positive effects in the structure of kidneys that exposure to poisoning after a period of treatment, Which improves tissue composition by maintaining the work of ribosomes, RNA strands and gene expression confirmed by Real Time (PCR), and40 has indicated that the treatment with doxycycline may help to prevent or remove some oxidative cases in the body such as oxidation of renal cells.

Lung

In the histology of lung to the animals not treated with castor bean powder, the air exchange zone consists of terminal bronchioles and some respiratory bronchioles containing Alveoli which spreading among the blood vessels. These bronchioles lead to the alveolar ducts, that leading to the alveolar sacs (Fig 9). While in the histological sections of animal lung treated with castor bean in the first group observed damage and destruction in the histological structure, blood cells appeared between the alveolar spaces and the proliferation of inflammatory cells that made the walls of the anomalies unclear and show necrosis in the epithelium tissue that lining bronchioles and some respiratory vesicle, as well as crash in the histological structure of the lung (Image 10). Some sources reported that castor bean poisoning leads to pathological effects and indicated that the effectiveness of ricin toxin causes high inflammation and change in broncho alveolar large fluid (BALF) with crash in Alveolar-capillary barrier51, there is also a dramatic increase in Neutrophils and macrophage in the lung, which may be the cause of these changes. Other sources have reported pulmonary poisoning due to pulmonary risinosis, Necrotizing pneumonia, bloating of the lymph nodes and the appearance of inflammation, which causes disruption of the tissue structure of the lung and collection of its fluid5,40,43. As well as the toxic plant effect that act on High retention of neutrophils and monocytes in the lung tissue, causing damage to their composition7, with the occurrence of generalized interstitial edema, pulmonary vascular leak, the peripheral respiratory distress syndrome and pulmonary tree extension2,14.

As for the treatment with doxycycline (25 mg/kg) in the second group had a simple effect did not significantly alter the damage caused by castor beans in the lung structure, where a breakdown of Vesicles barriers was found, whose walls were Expanded and filled with inflammatory cells, was also found resurfacing of red blood cell in the bronchioles (Image 11). In the transverse pulmonary section of the third group, the increased concentration of doxycycline showed significant improvement in the pulmonary tissue, Walls of the vesicles saved of their structure and clear alveolar ducts, as well as the disappearance of some damage to the tissue and maintenance the lining of Respiratory bronchioles and terminal bronchioles without dissolution (Image 12). observe7 that the treatment of Doxycycline can be used to
act as an antitoxin by reducing the toxicity of ricin and preventing acute respiratory distress syndrome, which reduces tissue and physiological changes within hours of use, also the doxycycline works to treat inflammation, tissue damage and regulate proinflammatory cytokine by its role as an anti-inflammatory agent, thus showing its role in a good response to the treatment of changes this is confirmed by the use of doxycycline for the prevention of pulmonary pneumonia and prolonged cell life during an experiment on mice.
