### Abstract

**Aim:** This study was undertaken to study the various histopathological patterns of ovarian lesions, their classification and relative distribution of these lesions.

**Methods:** The study was undertaken as a retrospective systematic study using existing patient data retrieved from the records of the Department of obstetrics and Gynecology, AIIMS, New Delhi, India. 200 ovarian mass specimens were received for evaluation, either as solitary specimens, or as part of total abdominal hysterectomy (TAH) specimens.

**Results:** Most patients were 10-39 years old. 20 (15%) instances were bilateral and 170 (85%) unilateral. 39 were symptomless. Hysterectomy specimens with salpingo-oophorectomy have associated findings. Leiomyoma and adenomyosis were most prevalent. Hydrosalpinx, chronic cervicitis, carcinoma endometrium, and carcinoma cervix were also found. Cystic follicle (14 instances), Follicular cyst, Par ovarian cyst (6 cases), hemorrhagic cyst, ectopic pregnancy, Torsion ovary, Inclusion cyst, and oophoritis did not cause cancer.

**Conclusion:** Several types of ovarian lesions have comparable clinical, radiological, and gross characteristics. Histopathology is the basis for diagnosing and classifying these lesions.

**Keywords:** Neoplastic Lesion, Non-neoplastic lesion, Ovary, Ovarian cyst, serous cystadenoma.

### Introduction

The ovaries are paired organs on either side of the uterus close to the lateral pelvic wall. A wide spectrum of pathological conditions – non-neoplastic and neoplastic can be seen in the ovary in routine surgical pathology. [1] Tumors of the ovary are a common neoplasm in women. [2] The most common lesions encountered in the ovary are functional or benign cysts and tumors. [3] Ovarian cancer is the sixth most common female cancer and is seen predominantly after the third decade of life. [4] Ovarian neoplasms are usually detected at a late stage and are large in size, because of their presentation with mild symptoms. [5] An accurate and early diagnosis of malignant lesions will go a long way in optimal management of these cases.

Ovaries are complex organs with unique physiology. The constant cyclical changes from puberty to menopause have made the ovary a site with a variety of cell types, each of which can give rise to tumors. [6,7] Though 80% of ovarian neoplasms are benign, the rest are malignant which causes significant mortality. [8] Malignant ovarian tumors represent the sixth most common cancer among females and the second most common

cancer of the female reproductive system. [9] India has the 2nd highest burden of ovarian cancers with poor survival outcomes, demonstrating low survival after 5 years (29%). [10]

Neoplastic lesions are categorized into Benign, Borderline and Malignant. The histogenesis of ovarian tumors revolves around the four main components namely Surface epithelium, Germ cell, Sex cord and Ovarian stroma, specialized and nonspecific. [11] There also are histologic differences in the type of tumors found in the younger and older populations, germ cell neoplasms predominate in prepubertal children and young adults, whereas lesions of epithelial origin are rare in this age group but are predominantly seen in elderly and postmenopausal women. Among all the ovarian neoplasm about 80% are benign having cystic, solid or mixed characteristics. [4] The remaining 20% of these tumors are malignant in nature leading to fatal prognosis. [12] Distinguishing non-neoplastic lesion from a neoplastic lesion is a challenge clinically and is important in guiding therapy. Even non neoplastic cystic lesions are also frequently responsible for a pelvic mass and associated with abnormal

hormonal manifestations often mimicking a neoplasm thus causing diagnostic confusion.

This study was undertaken to study the various histopathological patterns of ovarian lesions, their classification and relative distribution of these lesions.

### Methods

The study was undertaken as a retrospective systematic study using existing patient data retrieved from the records of the Department of obstetrics and Gynecology, AIIMS, New Delhi, India for two years. 200 ovarian mass specimens were received for evaluation, either as solitary specimens, or as part of total abdominal hysterectomy (TAH) specimens.

All samples were received from the operation theater in buffered formol saline as per protocols given in the Standard Operating Procedure (SOP)

for Histopathology of the Hospital. Samples were grossed on the same day that they were received, after ensuring adequate tissue fixation.

Tissue slices were taken and processed as per SOP. Microsections of 5 microns thickness were taken onto glass slides and stained by standard Hematoxylin and Eosin stains as per protocols. After mounting and labeling, all slides were viewed by at least two Pathologists before final reporting. All lesions were classified using WHO guidelines.

For the purpose of this study, all records pertaining to the study period were retrieved. Details of the histopathological diagnoses of the ovarian masses evaluated, as well as the age distribution of the patients, were analyzed. All patient data were kept confidential. Data was analyzed using an MS Excel worksheet and calculations of incidence made from the same.

### Results

**Table 1: Age wise distribution of patients operated for ovarian masses**

Age in years	Number of patients (total=200)	Patients (%)
<19	12	6
20-39	108	54
40-59 84 36.6%	70	35
>60	10	5

Majority of the Patients were in the age group of 10-39 years.

**Table 2: Laterality of ovarian Lesion**

Laterality	Side	Number & % age	Total No. & % age
Unilateral	Right	108(54)	170(85)
	Left	62(31)	
Bilateral		30(15)	30(15)

A total of 170(85%) cases were unilateral while 20(15%) cases were bilateral.

**Table 3: Clinical presentation of all the cases of Ovarian Lesions**

Clinical presentation	Number of cases
Pain Abdomen	75
Swelling abdomen	32
Pain abdomen and swelling abdomen	15
Abnormal uterine bleeding (AUB)	28
Pain abdomen and AUB	3
Infertility	15
Amenorrhea	2
Asymptomatic	30
Total	200

39 cases were asymptomatic. Associated findings in specimens of Hysterectomy with salpingo-oophorectomy were also found. Most common was leiomyoma either alone or in combination with adenomyosis. Other associated findings were chronic cervicitis, carcinoma endometrium, carcinoma cervix; hydrosalpinx etc.

**Table 4: Non-neoplastic lesions of ovary with laterality and number**

Types of cyst	Right	Left	Bilateral	Total
Cystic follicle(CF)	3	5	6	14
Follicular cyst(FC)	1	3	2	6
Corpus Luteal Cyst(CLC)	12	12	2	26
Hemorrhagic cyst(HC)	3	1	0	4
Endometriotic cyst(EMC)	11	6	4	21
Ectopic Gestation(EG)	1	1	0	2
Inclusion Cyst(IC)	2	0	0	2
Parovarian Cyst(PC)	4	2	0	6

Simple Cyst(SC)	12	9	0	21
Ovarian Abscess(OA)	0	1	0	1
Chronic nonspecific oophoritis(CO)	0	1	0	1
Xanthogranulomatous oophoritis(XO)	1	0	0	1
Torsion ovary	0	1	0	1

Other non-neoplastic lesion were Cystic follicle (14 cases), Follicular cyst and Parovarian cyst (6 cases each), hemorrhagic cyst, ectopic gestation, Torsion ovary, Inclusion cyst and oophoritis.

**Table 5: Neoplastic lesions with laterality and number**

Category of Neoplastic lesion	Type of Neoplastic Lesion	Right	Left	Bilateral	Total
<b>Benign</b>	Serous cystadenoma	31	9	0	40
	Dermoid cyst	11	5	2	18
	Mucinous Cystadenoma	7	4	0	11
	Serous Cyst adenofibroma	1	0	0	1
	Seromucous Cystadenoma	1	0	0	1
	Brenner Tumor	0	1	0	1
	Thecoma	1	0	0	1
	Benign Lipomatous lesion	1	0	0	1
<b>Borderline tumour</b>	Borderline Serous cystadenoma	2	0	0	2
	Atypical proliferative endometrioid tumor	0	1	0	1
<b>Malignant</b>	Serous carcinoma	2	0	1	3
	Endometrioid carcinoma	1	0	0	1
	Metastatic Carcinoma	0	0	3	3

Among the Benign lesion, Serous cystadenoma was the most commonly encountered lesion with 40 cases, followed by Dermoid cyst, and Mucinous cystadenoma, one case each of Serous Cyst adenofibroma, Seromucous cystadenoma, Brenner's tumor and Thecoma is also seen. Among Borderline lesions, two cases of Borderline Serous cystadenoma and one case of Atypical proliferative endometrioid tumor were recorded. Among the malignancies, Serous carcinoma was the most common comprising of three cases, while three cases of Metastatic carcinoma from different sites to bilateral ovary recorded. One case of Endometrioid carcinoma was also seen.

### Discussion

Ovarian lesions are unusual because of their diverse morphology and association with relatively mild symptoms. Neoplastic disorders can arise from (1) mullerian epithelium, (2) germ cells or (3) sex cord stromal cells. Tumors of the ovary are a common neoplasm in women. The most common lesions encountered in the ovary are functional or benign cysts and tumors. Typically, ovarian masses consist of functional and pathological lesions. [13] Given the location of these paired organs and the mildness of symptoms associated with lesions arising in them, these lesions usually attain a fairly large size before they are detected and removed. [14,15] Ovarian lesions are unusual because of their diverse morphology and association with relatively mild symptoms. Neoplastic disorders can arise from (1) mullerian epithelium, (2) germ cells

or (3) sex cord stromal cells. [16] In this study, it was identified that irrespective of the laterality, normal histology of ovaries including the presence of cortical inclusion cyst, corpus luteum, and corpus hemorrhagic was more frequently encountered than other non-neoplastic and neoplastic lesions in surgically resected specimens.

Overall most common age group affected were young reproductive female (21-30 years). Both non-neoplastic and neoplastic benign lesions were common to this age group. This is similar to other reports where most of the benign ovarian lesions occur in women of reproductive age groups. [13,17] Our study revealed that 170 out of 200 ovarian specimens were unilateral (85%) and only 20 (10.5%) were bilateral, similar to study by Gurung et al. (88.15% unilateral and 11.85% bilateral) [18] and Thakkar and Shah (88.4% unilateral). [19] Our findings vary slightly by the study done by Kanithkar et al. in which 78.18% tumors were unilateral and 21.82% tumours were bilateral. [20]

Grossly, it was found in our study that non-neoplastic as well as benign tumors were mostly cystic as compared to malignant, which were solid in consistency followed by partly cystic and partly solid which is in accordance with other studies. [21] In present study, out of 200 cases, 106 lesions were non-neoplastic (53%) while 94 lesions (47%) were neoplastic lesion. This is similar to study by Martinez-Onsurbe P et al. who reported 55 cases (41.67%) of non-neoplastic lesions, out of total 132

ovarian lesions and Kreuzer GF et al. reported 82 (40.39%) non-neoplastic lesions, out of 203 ovarian lesions. [22,23] Gurung et al. found 43.7% non-neoplastic lesions and 56.3% neoplastic lesion in their study. [18]

Among non-neoplastic lesions, Functional cysts were the most common lesions. Corpus luteal cysts including hemorrhagic corpus luteum cysts was the most commonly encountered ovarian lesions. This is followed by Simple cysts and Endometriotic cysts. This finding is similar to studies done by Choi and Kim where corpus luteum cyst was the most commonly encountered ovarian lesions. [23] In current study among 94 neoplastic lesions, 80 cases were benign, 6 cases were of borderline nature while 8 cases were malignant. This is in synchrony with the study of Sheikh et al. N Gupta et al. [24,25] while contradictory to study by Ahmad Z et al. where malignant lesion was comparatively high(40.6%). [26] In surface epithelial tumor, Serous Cystadenoma was the most common benign neoplasm followed by Mucinous Cystadenoma. This finding coincided with previous studies by Gupta et al. [25]

Borderline ovarian tumors are of low malignant potential having favorable prognosis and relatively early age at onset. [27] They comprise 4%–14% of all epithelial ovarian neoplasms. [28] In our study, we diagnosed 3 cases (3.6%) of borderline ovarian tumour including 2cases of Borderline serous papillary neoplasm and one case of Atypical proliferative endometrioid tumour. Metastases to the ovaries are relatively frequent with the most common being from the endometrium, breast, colon, stomach, and cervix. [29] Metastatic tumour (3 cases) constituted 3.61% of all the neoplastic ovarian lesion in our study and all of them were bilateral. Zaman et al. in his study reported single case of Metastatic tumour from breast. [30] Among sex-cord stromal tumour, a single case of Thecoma was diagnosed in our study.

### Conclusion

Despite being tiny, the ovary has a complex design with diverse cell types. It includes benign, borderline, and malignant lesions from non-neoplastic to neoplastic. Non-neoplastic and neoplastic ovarian lesions frequently have comparable clinical, radiological, and surgical characteristics. Ovarian tumour diagnosis and prognosis need histological research. Symptomatic therapy and monitoring may reduce surgery for benign functioning cysts that spontaneously resolve. Since most malignant cases are found later, early detection may improve patient survival and prognosis.
