ABSTRACT

Pharmaceutical drug delivery systems, ranging from oral solid dosage forms to transdermal patches, inhalers, injectable devices, and increasingly connected or smart delivery platforms, operate within one of the most tightly regulated product environments in the world. Regulatory bodies such as the United States Food and Drug Administration, the European Medicines Agency, and national authorities require manufacturers to demonstrate continuous, auditable control over product quality, data integrity, and process validation throughout the product lifecycle. Traditional, paper-based or fragmented compliance processes are increasingly unable to meet these expectations at the speed and scale demanded by modern pharmaceutical operations. This paper proposes an integrated, IT-enabled framework for regulatory compliance and quality management in pharmaceutical drug delivery systems. Adopting a conceptual, literature-based method, the paper synthesises regulatory requirements under 21 CFR Part 11, EU GMP Annex 11, and ICH Q10 with digital-transformation principles drawn from the Pharma 4.0 operating model to propose a five-layer framework comprising data integrity, electronic quality management, computerised system validation, real-time analytics, and regulatory interoperability. The framework is illustrated through its application to representative drug delivery technologies, including smart inhalers and connected injectable devices, and its potential benefits, namely improved audit readiness, reduced deviation-to-resolution time, and enhanced data integrity, are discussed alongside implementation challenges such as legacy system integration, validation burden, and cybersecurity risk. The paper concludes that IT-enabled quality architectures, when carefully validated and governed, can transform regulatory compliance from a reactive, documentation-heavy exercise into a proactive, data-driven capability that safeguards patient safety while supporting innovation in drug delivery.

Keywords: Regulatory Compliance; Quality Management System; Drug Delivery Systems; Pharma 4.0; Electronic Quality Management System (eQMS); Data Integrity

1. INTRODUCTION

Drug delivery systems occupy a critical position at the intersection of pharmaceutical formulation science, medical device engineering, and information technology. Modern delivery platforms, including transdermal patches, metered-dose and dry-powder inhalers, prefilled syringes, autoinjectors, and increasingly sensor-enabled or connected devices, must not only deliver a therapeutic agent with precision but must also be

manufactured, tested, and monitored under stringent Good Manufacturing Practice (GMP) and Good Distribution Practice (GDP) regimes. The convergence of pharmaceuticals and medical devices in combination products has further complicated the regulatory landscape, requiring manufacturers to satisfy overlapping drug and device compliance frameworks simultaneously (Malheiro et al., 2023).

Historically, quality management in pharmaceutical manufacturing relied heavily on paper-based batch records, manual deviation logs, and periodic, retrospective audits. This model, while familiar to regulators and manufacturers alike, has proven increasingly inadequate in the face of globalised supply chains, high-mix low-volume manufacturing, and the growing complexity of drug delivery devices (Qualio, 2023). Fragmented documentation across disconnected systems creates information silos that slow batch release, obscure emerging quality trends, and increase the risk of audit findings and regulatory warning letters (eLeaP Quality, 2026).

In response, regulators themselves have progressively encouraged the adoption of validated computerised systems and electronic records. The United States Food and Drug Administration's 21 CFR Part 11 and the European Union's EudraLex Volume 4, Annex 11 establish the criteria under which electronic records and electronic signatures may substitute for paper documentation, provided that systems demonstrate appropriate access controls, audit trails, and data integrity safeguards (U.S. Food and Drug Administration, 2003; European Commission, 2011). The International Council for Harmonisation's ICH Q10 pharmaceutical quality system guideline further frames quality management as a lifecycle activity spanning development, technology transfer, commercial manufacturing, and product discontinuation, rather than a discrete, end-of-line inspection function (International Council for Harmonisation, 2008).

Building on this regulatory foundation, the pharmaceutical industry has begun to embrace the broader digital-transformation paradigm known as Pharma 4.0, an adaptation of Industry 4.0 principles, including the Internet of Things (IoT), artificial intelligence, big data analytics, and cyber-physical systems, to the unique constraints of regulated drug manufacturing (International Society for Pharmaceutical Engineering, n.d.). For drug delivery systems specifically, this digital shift is particularly consequential: connected inhalers and injectors can now capture real-time usage and performance data, while manufacturing lines for such devices increasingly rely on networked sensors and automated in-process controls (Arief et al., 2022). Yet the literature has offered comparatively limited guidance on how these digital capabilities can be systematically organised into a coherent compliance and quality architecture specific to drug delivery systems, as distinct from pharmaceutical manufacturing in general. This paper addresses that gap by proposing an integrated, IT-enabled framework for regulatory compliance and quality management tailored to the particular demands of drug delivery technologies.

The remainder of the paper is organised as follows. Section 2 outlines the conceptual, literature-based method used to develop the framework. Section 3 presents the regulatory landscape governing drug delivery systems, examines the limitations of conventional compliance approaches, and details the proposed five-layer IT-enabled framework, illustrating its application to representative delivery technologies and discussing associated benefits and implementation challenges. Section 4 concludes with a summary of findings and directions for future research.

2. METHOD

This paper adopts a conceptual, literature-based research method appropriate to framework-development studies in regulatory and quality-management scholarship. Primary regulatory instruments, including 21 CFR Part 11 (U.S. Food and Drug Administration, 2003), EudraLex Volume 4, Annex 11 (European Commission, 2011), ICH Q10 (International Council for Harmonisation, 2008), and the GAMP 5 guidance on risk-based validation of GxP computerised systems (International Society for Pharmaceutical Engineering, 2022), were reviewed to identify the core compliance obligations applicable to computerised systems used in pharmaceutical manufacturing and quality operations. These primary sources were supplemented by peer-reviewed literature on Pharma 4.0 and digital transformation in pharmaceutical manufacturing (Arief et al., 2022; Malheiro et al., 2023; Romero-Torres, 2021), as well as professional and industry guidance on electronic quality management systems and GxP-compliant software architecture (eLeaP Quality, 2026; Qualio, 2023).

Drawing on these sources, the paper synthesises common structural elements identified across the literature, namely data integrity controls, electronic documentation and workflow management, computerised system validation, analytics-driven quality monitoring, and regulator-facing reporting, into a single, layered conceptual framework. The framework was then examined against representative categories of drug delivery systems (oral solid dosage, transdermal, inhalation, and injectable/connecting devices) to assess its applicability and to surface implementation considerations specific to each category. As a conceptual paper, this study does not involve primary data collection, survey instruments, or statistical analysis; its contribution lies in the synthesis and structuring of existing regulatory and technical knowledge into an actionable framework, with validation of the framework's practical effectiveness left to future empirical research.

3. RESULTS AND DISCUSSION

3.1 Regulatory Landscape Governing Drug Delivery Systems

Drug delivery systems are subject to a layered regulatory architecture. At the foundation lie Good Manufacturing Practice requirements, which in the United States are codified in 21 CFR Parts 210 and 211, and internationally through World Health Organization GMP guidance and ICH quality guidelines (International Council for Harmonisation, 2008). Where a drug delivery system qualifies as a combination product, such as a prefilled autoinjector or a drug-eluting device, manufacturers must additionally satisfy device-quality requirements analogous to ISO 13485, which governs quality management systems for medical devices (International Organization for Standardization, 2016). Layered atop these product-quality requirements are computerised-systems regulations, principally 21 CFR Part 11 and EU Annex 11, which apply whenever electronic records or electronic signatures are used to satisfy any of the underlying GMP or device-quality obligations (U.S. Food and Drug Administration, 2003; European Commission, 2011). Table 1 summarises the core instruments comprising this regulatory architecture.

Table 1
Core Regulatory Instruments Governing Drug Delivery Systems

Instrument	Issuing Body / Jurisdiction	Primary Scope	Key Requirement
21 CFR Part 11	US FDA (United States)	Electronic records and electronic signatures	Audit trails, access controls, validated systems for e-records
EU Annex 11	European Commission (EU)	Computerised systems used in GMP activities	Risk-based validation, data integrity, system security
ICH Q10	ICH (International)	Pharmaceutical quality system, lifecycle-wide	Continuous process verification and management review

Instrument	Issuing Body / Jurisdiction	Primary Scope	Key Requirement
GAMP 5	ISPE (International)	Validation of GxP computerised systems	Proportionate, risk-based system validation approach
ISO 13485: 2016	ISO (International)	Medical device quality management	Applies to combination /device-based delivery systems

A recurring theme across this regulatory architecture is the expectation of demonstrable data integrity. Regulators increasingly assess data integrity against the ALCOA+ principles, requiring that records be Attributable, Legible, Contemporaneous, Original, Accurate, and additionally Complete, Consistent, Enduring, and Available (Qualio, 2023). For drug delivery systems, whose manufacturing frequently involves high-speed, automated assembly and in-line inspection, the volume and velocity of quality-relevant data generated can be substantially greater than for simpler dosage forms, making manual, paper-based data capture increasingly impractical (Malheiro et al., 2023).

3.2 Limitations of Traditional Compliance Approaches

Conventional, paper-centric or partially digitised compliance approaches exhibit several structural weaknesses when applied to contemporary drug delivery manufacturing. First, disconnected systems for document control, training records, change control, and corrective and preventive action (CAPA) management create information silos that obscure cross-functional quality signals and slow root-cause investigation (eLeaP Quality, 2026). Second, manual transcription between paper batch records and enterprise systems introduces transcription error risk and undermines the contemporaneous and accurate criteria of data integrity. Third, retrospective, sampling-based quality review, in which a limited subset of batch records is audited after the fact, is poorly suited to detecting subtle process drifts in automated, high-throughput assembly lines typical of inhaler or injector manufacturing. Fourth, and perhaps most consequentially for multinational manufacturers, paper-based systems complicate the harmonisation of compliance evidence across multiple regulatory jurisdictions, each of which may request evidence in

different formats and within different timeframes (Interfacing, 2025).

These limitations are amplified for drug delivery systems that incorporate embedded electronics or connectivity features, such as sensor-equipped inhalers that log dose timing and technique. Such devices generate continuous streams of usage and performance data that fall outside the scope of traditional batch-record documentation altogether, yet may nonetheless be relevant to post-market surveillance and pharmacovigilance obligations. Traditional compliance architectures, designed primarily around discrete, batch-oriented manufacturing records, are not naturally equipped to capture, validate, and act upon this continuous data stream. Figure 2 contrasts the traditional, largely sequential compliance workflow with the parallel, system-driven workflow enabled by the framework proposed in Section 3.3.

Figure 2. Comparison of Traditional and IT-Enabled Regulatory Compliance Workflows
3.3 Proposed IT-Enabled Compliance and Quality Management Framework

To address these limitations, this paper proposes a five-layer, IT-enabled framework for regulatory compliance and quality management in pharmaceutical drug delivery systems. The five layers, namely Data Integrity and Access Control, Electronic Quality Management, Computerised System Validation, Real-Time Analytics and Predictive Quality, and Regulatory Interoperability, are designed to operate as an integrated architecture rather than as independent, siloed tools, as illustrated in Figure 1.

Figure 1. Five-Layer IT-Enabled Regulatory Compliance and Quality Management Framework

Layer 1: Data Integrity and Access Control

The foundational layer establishes the technical controls necessary to satisfy ALCOA+ and 21 CFR Part 11 requirements across all systems that generate or store GxP-relevant data, including manufacturing execution systems, laboratory information management systems, and device-level firmware logs. Core controls include role-based access permissions, unique user authentication, tamper-evident and time-stamped audit trails for every data entry, modification, and deletion, and validated backup and disaster-recovery procedures (Miratag, 2026). For drug delivery devices with embedded connectivity, this layer extends to secure, encrypted data transmission from the device to centralised repositories, ensuring that usage and performance data remain attributable and unaltered from point of capture to point of review.

Layer 2: Electronic Quality Management (eQMS)

The second layer digitises the core processes of the pharmaceutical quality system as defined by ICH Q10, including document control, deviation and CAPA management, change control, training management, and supplier qualification, within a single, integrated electronic quality management system (Dot Compliance, 2025). By centralising these workflows, an eQMS eliminates the information silos characteristic of fragmented, paper-based approaches and enables cross-functional visibility into emerging quality trends. Automated workflow routing, for example, triggering a supplier-qualification task whenever a new component supplier is referenced in an updated standard operating procedure, further reduces the administrative burden historically associated with maintaining an audit-ready quality system (IntuitionLabs, 2026).

Layer 3: Computerised System Validation (CSV/CSA)

Because every system within Layers 1 and 2 constitutes a GxP computerised system, the third layer applies a risk-based validation methodology, consistent with GAMP 5, to establish and maintain documented evidence that each system performs as intended (International Society for Pharmaceutical Engineering, 2022). This layer governs the qualification of manufacturing execution systems, eQMS platforms, laboratory instrumentation software, and, where applicable, the embedded software of connected drug delivery devices themselves. A risk-based approach allows validation effort to be proportionate to patient-safety and data-integrity risk, avoiding the historically common problem of excessive, low-value validation documentation that slows system deployment without commensurate quality benefit.

Layer 4: Real-Time Analytics and Predictive Quality

The fourth layer leverages the data aggregated through Layers 1 through 3, together with in-line process analytical technology (PAT) sensor data from automated assembly and filling lines, to support real-time and predictive quality monitoring. Statistical process control dashboards, machine-learning-based anomaly detection, and predictive maintenance algorithms allow manufacturers to identify process drift and equipment degradation before they manifest as out-of-specification results or product defects (Arief et al., 2022). For drug delivery systems specifically, this layer can incorporate device-level usage analytics gathered from connected inhalers or injectors, enabling proactive identification of device performance issues that might otherwise only surface through post-market complaints.

Layer 5: Regulatory Interoperability

The outermost layer manages the interface between the internal quality architecture and external regulatory stakeholders. This includes structured, standards-based electronic submission of quality data to regulatory authorities, automated generation of audit-ready evidence packages, and interoperability with pharmacovigilance and post-market surveillance databases for connected devices. By designing regulatory interoperability as an explicit architectural layer, rather than a manual, ad hoc reporting exercise performed at the time of inspection, manufacturers can substantially reduce the time and resource burden associated with regulatory submissions and inspections (Interfacing, 2025).

3.4 Illustrative Application to Drug Delivery Technologies

Applying the framework to representative drug delivery categories illustrates its adaptability. For transdermal patch manufacturing, Layers 1 through 3 address the high-volume, continuous coating and

lamination processes typical of patch production, where in-line thickness and adhesion sensors generate substantial process data requiring validated capture and review. For metered-dose and dry-powder inhalers, Layer 4 analytics can be applied to in-line leak and dose-uniformity testing data to detect early signs of valve or actuator wear across a production run. For prefilled syringes and autoinjectors, Layers 1 and 3 are particularly significant given the combination-product status of many such devices, requiring validated computerised systems that satisfy both pharmaceutical GMP and medical-device quality requirements simultaneously (International Organization for Standardization, 2016). For emerging connected or smart delivery devices, such as sensor-enabled inhalers that log inhalation technique and adherence, all five layers operate in concert: device-generated data is captured with integrity controls (Layer 1), reviewed through the eQMS for deviation management (Layer 2), supported by validated device firmware and data-pipeline systems (Layer 3), analysed for performance and adherence trends (Layer 4), and, where relevant, fed into post-market surveillance reporting to regulators (Layer 5). Table 2 summarises the applicability of each framework layer across these delivery categories.

Table 2

Applicability of Framework Layers Across Drug Delivery Categories

Framework Layer	Trans dermal	Inhal ation	Inject able / Autoinjector	Conn ected / Smart Device
Layer 1: Data Integrity & Access Control	✓	✓	✓	✓
Layer 2: Electronic Quality Management	✓	✓	✓	✓

Framework Layer	Transdermal	Inhalation	Injectable / Autoinjector	Connected / Smart Device
Layer 3: Computerised System Validation	✓	✓	✓	✓
Layer 4: Real-Time Analytics & Predictive Quality	✓	✓	Limited	✓
Layer 5: Regulatory Interoperability	Limited	Limited	✓	✓

3.5 Benefits and Implementation Challenges

The literature reviewed for this paper suggests that organisations adopting integrated, IT-enabled quality architectures of the kind proposed here report measurable benefits, including reduced batch-release cycle times, improved first-time-right documentation rates, and substantially faster retrieval of audit evidence during regulatory inspections (IntuitionLabs, 2026; Qualio, 2023). By shifting from retrospective, sample-based review to continuous, system-driven monitoring, manufacturers can also identify and address quality issues earlier in the production cycle, reducing the incidence and severity of deviations. Table 3 summarises these benefits alongside the corresponding implementation challenges identified in the literature.

Table 3

Benefits and Implementation Challenges of the IT-Enabled Framework

Benefits of the IT-Enabled Framework	Associated Implementation Challenges
Reduced batch-release cycle time through automated, continuous documentation	Integration effort and cost for legacy manufacturing execution and laboratory systems
Improved first-time-right documentation and fewer transcription errors	Validation burden if risk-based CSV/CSA principles are not properly applied
Faster retrieval of audit-ready evidence during inspections	Cybersecurity exposure for connected, data-transmitting delivery devices
Earlier detection of process drift via real-time and predictive analytics	Organisational change management and staff retraining requirements
Stronger, demonstrable data integrity aligned with ALCOA+ principles	Harmonising evidence formats across multiple regulatory jurisdictions

Nonetheless, implementation of such a framework is not without challenges, as Table 3 indicates. Legacy manufacturing execution and laboratory systems, particularly at established manufacturing sites, may require substantial integration effort or replacement to participate fully in an integrated architecture. The validation burden associated with qualifying a growing number of interconnected computerised systems, if not managed through a genuinely risk-based approach, can itself become a source of delay and cost (International Society for Pharmaceutical Engineering, 2022). Cybersecurity represents a further significant concern, particularly for connected drug delivery devices that transmit data outside the traditional manufacturing-site perimeter, where the confidentiality, integrity, and availability of both manufacturing and patient-usage data must be protected against unauthorised access. Finally, organisational change management, including retraining quality and manufacturing personnel accustomed to paper-based workflows, is frequently cited in the literature as a critical, and often underestimated, determinant of successful digital quality transformation (Romero-Torres, 2021).

4. CONCLUSION

This paper has proposed an integrated, five-layer, IT-enabled framework for regulatory compliance and quality management tailored to the particular demands of pharmaceutical drug delivery systems. By synthesising the requirements of 21 CFR Part 11, EU Annex 11, ICH Q10, and GAMP 5 with the digital-transformation principles of Pharma 4.0, the framework offers a structured pathway for manufacturers to move from fragmented, paper-based compliance practices toward a proactive, data-driven quality architecture spanning data integrity, electronic quality management, computerised system validation, real-time analytics, and regulatory interoperability. Applied to representative categories of drug delivery technology, including transdermal, inhalation, injectable, and connected devices, the framework demonstrates both broad applicability and the need for category-specific implementation considerations.

The analysis also indicates that realising the framework's benefits, namely improved audit readiness, faster deviation resolution, and stronger data integrity, requires manufacturers to address non-trivial implementation challenges, including legacy system integration, proportionate risk-based validation, cybersecurity for connected devices, and organisational change management. Future research should empirically test the proposed framework within specific manufacturing environments, examine its cost-benefit profile relative to conventional compliance approaches, and explore how emerging technologies such as artificial intelligence-based anomaly detection and blockchain-enabled supply chain traceability might further strengthen the regulatory interoperability layer of IT-enabled quality architectures for pharmaceutical drug delivery systems.
